ABSTRACT

Background

Since December 2019, the world has struggled with the COVID-19 pandemic. Even after the introduction of various vaccines, this disease still takes a considerable toll. In order to improve the optimal allocation of resources and communication of prognosis, healthcare providers

and patients need an accurate understanding of factors (such as obesity) that are associated with a higher risk of adverse outcomes from the COVID-19 infection.

Objectives

To evaluate obesity as an independent prognostic factor for COVID-19 severity and mortality among adult patients in whom infection with the COVID-19 virus is confirmed.

Search methods

MEDLINE, Embase, two COVID-19 reference collections, and four Chinese biomedical databases were searched up to April 2021.

Selection criteria

We included case-control, case-series, prospective and retrospective cohort studies, and secondary analyses of randomised controlled trials if they evaluated associations between obesity and COVID-19 adverse outcomes including mortality, mechanical ventilation, intensive care unit (ICU) admission, hospitalisation, severe COVID, and COVID pneumonia. Given our interest in ascertaining the independent association between obesity and these outcomes, we selected studies that adjusted for at least one factor other than obesity. Studies were evaluated for inclusion by two independent reviewers working in duplicate.

Data collection and analysis

Using standardised data extraction forms, we extracted relevant information from the included studies. When appropriate, we pooled the estimates of association across studies with the use of random-effects meta-analyses. The Quality in Prognostic Studies (QUIPS) tool provided the platform for assessing the risk of bias across each included study. In our main comparison, we conducted meta-analyses for each obesity class separately. We also meta-analysed unclassified obesity and obesity as a continuous variable (5 kg/m² increase in BMI (body mass index)). We used the GRADE framework to rate our certainty in the importance of the association observed between obesity and each outcome. As obesity is closely associated with other comorbidities, we decided to prespecify the minimum adjustment set of variables including age, sex, diabetes, hypertension, and cardiovascular disease for subgroup analysis.

Main results

We identified 171 studies, 149 of which were included in meta-analyses. As compared to 'normal' BMI (18.5 to 24.9 kg/m²) or patients without obesity, those with obesity classes I (BMI 30 to 35 kg/m²), and II (BMI 35 to 40 kg/m²) were not at increased odds for mortality (Class I: odds ratio [OR] 1.04, 95% confidence interval [CI] 0.94 to 1.16, high certainty (15 studies, 335,209 participants); Class II: OR 1.16, 95% CI 0.99 to 1.36, high certainty (11 studies, 317,925 participants)). However, those with class III obesity (BMI 40 kg/m² and above) may be at increased odds for mortality (Class III: OR 1.67, 95% CI 1.39 to 2.00, low certainty, (19 studies, 354,967 participants)) compared to normal BMI or patients without obesity. For mechanical ventilation, we observed increasing odds with higher classes of obesity in comparison to normal BMI or patients without obesity (class I: OR 1.38, 95% CI 1.20 to 1.59, 10 studies, 187,895 participants, moderate certainty; class II: OR 1.67, 95% CI 1.42 to 1.96, 6 studies, 171,149 participants, high certainty; class III: OR 2.17, 95% CI 1.59 to 2.97, 12 studies, 174,520 participants, high certainty). However, we did not observe a dose-response relationship across increasing obesity classifications for ICU admission and hospitalisation.

Authors' conclusions

Our findings suggest that obesity is an important independent prognostic factor in the setting of COVID-19. Consideration of obesity may inform the optimal management and allocation of limited resources in the care of COVID-19 patients.

PLAIN LANGUAGE SUMMARY

Obesity and adverse COVID-19 outcomes

What are the effects of obesity on COVID-19 outcomes?

Key messages

- There is enough evidence to support the finding that extreme obesity (BMI > 40 kg/m²) increases the chance of a person dying, requiring a breathing tube, being hospitalised, and being admitted to the ICU due to COVID-19.
- Obesity in general will result in a person requiring a breathing tube.
- The higher one's BMI gets, the higher the chance that a person will suffer from severe COVID-19 disease.

What is obesity?

Obesity is defined as abnormal or excessive fat accumulation in different parts of the human body and it presents a risk to health. To assess obesity, different indices such as body mass index (BMI) can be used, which is one's weight in kilograms divided by the square of height in

metres. The WHO has classified obesity into three classes. According to this classification, class I obesity includes a BMI ranging from 30 to 35 kg/m², class II from 35 to 40 kg/m², and class III from 40 kg/m² and more.

What did we want to find out?

We wanted to find out whether obesity has any effects on mortality, requiring a breathing tube, hospitalisation, ICU admission, severe disease or pneumonia due to COVID-19 disease.

What did we do?

We conducted a systematic search in medical databases for evidence looking at the association of obesity and mortality and other outcomes from December 2019 to April 2021. We then categorised and rated these findings based on our confidence in the evidence, study size, and quality.

What did we find?

We identified 171 eligible studies, with 149 studies (12,045,976 participants) providing quantitative data for at least one of our meta-analyses. In terms of the outcomes, 111 studies reported on mortality, 48 on requiring a breathing tube, 47 on ICU admission, 34 on hospitalisation, 32 on severe COVID-19, six on pneumonia, five on length of hospitalisation, two on length of ICU admission, and one on the duration of the requirement of a breathing tube.

Main results

Our findings indicate that there is a high certainty of evidence that class III obesity is associated with an increased risk of mortality among COVID-19 patients. However, we found that, in mild cases of obesity (classes I and II), this factor might not be independently associated with increased risk of mortality in COVID-19 patients. Similarly, we are very certain that obesity is an independent important factor associated with the risk of requiring a breathing tube in COVID-19 patients. However, the effect estimate sizes were not consistent with a dose-response relationship across increasing obesity classes for ICU admission, hospitalisation, severe COVID-19 disease and pneumonia. To conclude, this review investigated the potential association between obesity and adverse COVID-19 outcomes. We were able to gather evidence from multiple studies and concluded that the association of obesity with mortality and requiring a breathing tube is of high certainty.

What are the limitations of the evidence?

Although BMI is a widely used measurement, the relationship between BMI and body fat is non-linear. Moreover, our review did not discriminate against self-reported and measured BMI. Finally, we were unable to keep up with the rapid pace of publications on COVID-19 despite our best efforts.

How up-to-date is the evidence?

The evidence is up-to-date to April 2021.

SUMMARY OF FINDINGS

Summary of findings 1. Obesity Class I compared to Normal Weight or Non-Obese for Adults with COVID-19

Obesity class I ($30 \text{ kg/m}^2 \leq \text{BMI} < 35 \text{ kg/m}^2$) compared to normal BMI or patients with a $\text{BMI} < 30 \text{ kg/m}^2$ for adults with COVID-19

Patient or population: Adults with COVID-19

Settings: Community and in-hospital

Outcomes <i>Time frame of absolute effects</i>	Absolute effects from study(ies)* (95% CI)			Relative effect 95% CI	No of Participants (studies)	Quality of the evidence (GRADE)	Plain language summary
	Normal BMI or Non-Obese	Obesity Class I	Difference with Obesity Class I				
Mortality (in-hospital)	180 per 1000	186 per 1000	6 more per 1000 (9 fewer to 23 more)	Odds Ratio: 1.04(CI 95% 0.94 to 1.16) ¹	335,209 (15)	⊕⊕⊕ HIGH ²	Obesity class I has little or no difference on mortality.
Mechanical ventilation (in-hospital)	198 per 1000	254 per 1000	56 more per 1000 (31 more to 84 more)	Odds Ratio: 1.38(CI 95% 1.2 to 1.59) ³	187,895 (10)	⊕⊕⊕ MODERATE ⁴	Obesity class I probably increases the risk of mechanical ventilation.
ICU admission (in-hospital)	208 per 1000	263 per 1000	55 more per 1000 (10 more to 107 more)	Odds Ratio: 1.36(CI 95% 1.06 to 1.75) ⁵	162,741 (7)	⊕⊕⊕ MODERATE ⁶	Obesity class I probably increases the risk of ICU admission.
Hospitalisation (30-days, community)	146 per 1000	141 per 1000	5 fewer per 1000 (23 fewer to 17 more)	Odds Ratio: 0.96(CI 95% 0.82 to 1.14) ⁷	515,155 (5)	⊕⊕⊕ MODERATE ⁸	Obesity class I probably has little or no difference on the risk of hospitalisation.
Severe COVID-19 (in-hospital)	158 per 1000	217 per 1000	59 more per 1000 (21 more to 102 more)	Odds Ratio: 1.48(CI 95% 1.16 to 1.87) ⁹	1040 (3)	⊕⊕⊕ LOW ¹⁰	Obesity class I may increase the risk of severe Covid-19.
Pneumonia	-	-	-	-	-	-	No studies were found that looked at the impact of obesity class I on pneumonia.

*The basis for the **control group absolute risks** from the study(ies) is mean risk across study(ies) unless otherwise stated in comments. The **intervention absolute risk and difference** is based on the risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

GRADE Working User Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
Very low quality: We are very uncertain about the estimate.

1. Systematic review. Baseline/comparator control arm of reference used for intervention.
2. No reasons to rate down.
3. Systematic review. Baseline/comparator control arm of reference used for intervention.
4. Imprecision: serious. The lower bound 95% CI crossed our absolute risk difference of 50 per 1000 patients followed.
5. Systematic review. Baseline/comparator control arm of reference used for intervention.
6. Inconsistency: serious. Lack of overlap in point estimates and 95% CI across studies. Our subgroup analyses failed to explain the observed heterogeneity. Low credibility (based on ICEMAN) for one statistically significant subgroup analysis based on the reference group.
7. Systematic review. Baseline/comparator control arm of reference used for intervention.
8. Inconsistency: serious. A significant subgroup effect was observed based on the adjustment criteria. The credibility of this subgroup effect, however, was low (based on ICEMAN).
9. Systematic review. Baseline/comparator control arm of reference used for intervention.
10. Risk of Bias: serious. 2 of 3 studies were at an overall high risk of bias. Imprecision: serious. The lower bound 95% CI crossed our prespecified absolute risk difference threshold of 50 per 1000 patients followed.

Note: BMI - Body Mass Index; CI - Confidence Interval; GRADE - Grading of Recommendations, Assessment, Development and Evaluations

Summary of findings 2. Obesity Class II compared to Normal Weight or Non-Obese for Adults with COVID-19

Obesity Class II ($35 \text{ kg/m}^2 \leq \text{BMI} < 40 \text{ kg/m}^2$) compared to normal BMI or patients with a BMI $< 30 \text{ kg/m}^2$ for adults with COVID-19

Patient or population: Adults with COVID-19

Settings: Community and in-hospital

Outcomes <i>Time frame of absolute ef- fects</i>	Absolute effects from study(ies)* (95% CI)			Relative effect 95% CI	No of Participants (studies)	Quality of the evidence (GRADE)	Plain language summary
	Normal BMI or Non-Obese	Obesity Class II	Difference with Obesity Class II				
Mortality (in-hospital)	180 per 1000	203 per 1000 (178 to 244)	23 more per 1000 (1 fewer to 50 more)	Odds Ratio: 1.16(CI 95% 0.99 to 1.36) ¹	317,925 (11)	⊕⊕⊕⊕ HIGH ²	Obesity class II has little or no difference on the risk of mortality.
Mechanical ventilation (in-hospital)	198 per 1000	292 per 1000 (281 to 388)	94 more per 1000 (62 more to 128 more)	Odds Ratio: 1.67(CI 95% 1.42 to 1.96) ³	171,149 (6)	⊕⊕⊕⊕ HIGH ⁴	Obesity class II increases the risk of mechanical ventilation.

ICU admission (in-hospital)	208 per 1000	211 per 1000 (187 to 239)	3 more per 1000 (17 fewer to 24 more)	Odds Ratio: 1.02(CI 95% 0.9 to 1.15) ⁷	157,665 (4)	⊕ ⊕ ⊖ ⊖ LOW ⁶	Obesity class II may have little or no differ- ence in the risk of ICU admission.
Hospitalisation (30-days, com- munity)	209 per 1000	216 per 1000 (188 to 250)	7 more per 1000 (17 fewer to 32 more)	Odds Ratio: 1.04(CI 95% 0.9 to 1.2) ⁹	293,707 (3)	⊕ ⊕ ⊖ ⊖ MODERATE ⁸	Obesity class II probably has little or no difference on the risk of hospitalisation.
Severe COVID	-	-	-	-	-	-	No studies were found that looked at the impact of obesity class II on severe COVID.
Pneumonia	-	-	-	-	-	-	No studies were found that looked at the impact of obesity class II on pneumonia.

*The basis for the **control group absolute risks** from the study(ies) is mean risk across study(ies) unless otherwise stated in comments. **The intervention absolute risk and difference** is based on the risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

1. Systematic review. Baseline/comparator control arm of reference used for intervention.
 2. No reasons to rate down.
 3. Systematic review. Baseline/comparator control arm of reference used for intervention.
 4. No reasons to rate down.
 5. Systematic review. Baseline/comparator control arm of reference used for intervention.
 6. Risk of Bias: very serious. There were only 4 studies in the meta-analysis and about 70% of the total study weights came from the 3 studies at a high risk of bias.
 7. Systematic review. Baseline/comparator control arm of reference used for intervention.
 8. Inconsistency: serious. One study that did not adjust for the prespecified adjustment set and was at low risk of bias showed a statistically significant larger effect size. The credibility of this subgroup effect, however, was low (based on ICEMAN). Therefore, we decided to rate down for inconsistency.
- Note: BMI - Body Mass Index; CI - Confidence Interval; GRADE - Grading of Recommendations, Assessment, Development and Evaluations

Summary of findings 3. Obesity Class III compared to Normal BMI, Non-obese, or BMI < 40 for Adults with COVID-19

Obesity class III ($BMI \geq 40 \text{ kg/m}^2$) compared to normal weight, patients with a $BMI < 30 \text{ kg/m}^2$, or $BMI < 40$ for adults with COVID-19

Patient or population: Adults with COVID-19

Settings: Community and in-hospital

Outcomes Time frame of ab-solute effects	Absolute effects from study(ies)* (95% CI)			Relative effect 95% CI	No of Participants (studies)	Quality of the evidence (GRADE)	Plain language summary
	Normal BMI, Non-obese, or BMI < 40	Obesity Class III	Difference with Obesity Class III				
Mortality (in-hospital)	180 per 1000	268 per 1000 (250 to 360)	88 more per 1000 (54 more to 125 more)	Odds Ratio: 1.67 (CI 95% 1.39 to 2.0) ¹	354,967 (19)	⊕⊕⊖ LOW ²	Obesity class III may increase the risk of mortality.
Mechanical ventila-tion (in-hospital)	198 per 1000	349 per 1000 (314 to 588)	151 more per 1000 (84 more to 225 more)	Odds Ratio: 2.17 (CI 95% 1.59 to 2.97) ³	174,520 (11)	⊕⊕⊕ HIGH ⁴	Obesity class III increases the risk of mechanical ventilation.
ICU admission (ad-justed for at least DM, HTN, cardiovas-cular disease, age, and sex) (in-hospital)	208 per 1000	240 per 1000 (201 to 309)	32 more per 1000 (5 fewer to 73 more)	Odds Ratio: 1.2 (CI 95% 0.97 to 1.49) ⁵	155,405 (3)	⊕⊕⊕⊖ MODERATE ⁶	Obesity class III probably has little or no difference on the risk of ICU admis-sion when adjusted for DM, HTN, car-diovascular disease, age, and sex.
Hospitalisation (ad-justed for DM, HTN, cardiovascular dis-ease, age, and sex) (30-days, community)	243 per 1000	302 per 1000 (289 to 369)	59 more per 1000 (33 more to 85 more)	Odds Ratio: 1.35 (CI 95% 1.19 to 1.52) ⁷	293,004 (4)	⊕⊕⊖ LOW ⁸	Obesity class III may increase the risk of hospitalisation when adjusted for DM, HTN, cardiovascular disease, age, and sex.
ICU admission (in-hospital)	208 per 1000	372 per 1000 (270 to 488)	164 more per 1000 (62 more to 280 more)	Odds Ratio: 2.26 (CI 95% 1.41 to 3.63)	15,691 (7)	⊕⊕⊖ LOW ⁹	Obesity class III may increase the risk of ICU admission.
Hospitalisation (30-days, community)	243 per 1000	362 per 1000 (310 to 420)	119 more per 1000 (67 more to 177 more)	Odds Ratio: 1.77 (CI 95% 1.4 to 2.26)	747,176 (7)	⊕⊕⊖ LOW ¹⁰	Obesity class III may increase the risk of hospitalisation.

Severe COVID	-	-	-	-	-	No studies were found that looked at the impact of obesity class III on severe COVID.
--------------	---	---	---	---	---	---

.Pneumonia	-	-	-	-	-	No studies were found that looked at the impact of obesity class III on pneumonia.
------------	---	---	---	---	---	--

*The basis for the **control group absolute risks** from the study(ies) is mean risk across study(ies) unless otherwise stated in comments. **The intervention absolute risk and difference** is based on the risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

GRADE Working UserGroup grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

1. Systematic review. Baseline/comparator control arm of reference used for intervention.
2. Inconsistency: serious. The visual inspection of the forest plot indicated considerable CIs not overlapping with a high I squared value. None of the prespecified subgroup analyses could explain the heterogeneity. Publication bias: serious. Asymmetrical funnel plot.
3. Systematic review. Baseline/comparator control arm of reference used for intervention.
4. No reasons to rate down.
5. Systematic review. Baseline/comparator control arm of reference used for intervention.
6. Imprecision: serious. The confidence interval for absolute risk difference crossed the prespecified threshold of 50 per 1000 COVID patients.
7. Systematic review. Baseline/comparator control arm of reference used for intervention.
8. Inconsistency: serious. Two studies had non-overlapping CIs. The I-squared value was considerably high. Imprecision: serious. A sensitivity analysis that omits the two studies with different CIs changes the interpretation of the results, therefore, we decided to rate down for imprecision and inconsistency twice. The CI also crossed the prespecified threshold.
9. Risk of Bias: serious. More than 50% of the total weight of the analysis fell on the studies at a high risk of bias. Furthermore, the effect estimate from the low risk of bias studies was too wide to provide a basis for comparison with the overall effect estimate. Inconsistency: serious. The effect estimates from different studies had minimal overlapping confidence intervals with very different indications for interpretation of the results.
10. Inconsistency: very serious. The effect estimate CIs from different studies were very far apart from each other with each warranting different interpretations of the results.

Note: BMI - Body Mass Index; CI - Confidence Interval; GRADE - Grading of Recommendations, Assessment, Development and Evaluations

Summary of findings 4. Obesity (Unclassified) compared to Normal Weight or Non-Obese for Adults with COVID-19

Obesity (unclassified) compared to normal BMI or patients with a BMI < 30 kg/m² for adults with COVID-19

Patient or population: Adults with COVID-19

Settings: Community and in-hospital

Outcomes Time frame of ab- solute effects	Absolute effects from study(ies)* (95% CI)			Relative effect 95% CI	No of Participants (studies)	Quality of the evidence (GRADE)	Plain language summary
	Normal BMI or Non-Obese	Obesity (Un-classified)	Difference with Obesity (Unclassified)				
Mortality (in-hospital)	180 per 1000	229 per 1000 (230 to 255)	49 more per 1000 (39 more to 58 more)	Odds Ratio: 1.35 (CI 95% 1.28 to 1.42) ¹	1,307,520 (54)	⊕⊕⊖⊖ LOW ²	Obesity (unclassified) may have little or no difference on the risk of mortality.
Mechanical ventila- tion (in-hospital)	198 per 1000	294 per 1000 (285 to 394)	96 more per 1000 (64 more to 131 more)	Odds Ratio: 1.69 (CI 95% 1.44 to 1.99) ³	62,348 (21)	⊕⊕⊖⊖ LOW ⁴	Obesity (unclassified) may increase the risk of mechanical ventilation.
ICU admission (in-hospital)	208 per 1000	328 per 1000 (291 to 367)	120 more per 1000 (83 more to 159 more)	Odds Ratio: 1.86 (CI 95% 1.56 to 2.21) ⁵	70,529 (21)	⊕⊕⊕⊖ MODERATE ⁶	Obesity (unclassified) probably increases the risk of ICU admission.
Hospitalisation (adjusted for age, sex, DM, HTN, and cardiovascular dis- ease) <i>(30 days, communi- ty)</i>	257 per 1000	312 per 1000 (308 to 370)	55 more per 1000 (36 more to 75 more)	Odds Ratio: 1.31 (CI 95% 1.2 to 1.44) ⁷	510,405 (14)	⊕⊕⊕⊖ MODERATE ⁸	Obesity (unclassified) probably increases the risk of hospitalisation.
Severe COVID <i>(30-days, communi- ty)</i>	191 per 1000	314 per 1000 (309 to 443)	123 more per 1000 (86 more to 163 more)	Odds Ratio: 1.94 (CI 95% 1.62 to 2.32) ⁹	878,804 (19)	⊕⊕⊕⊕ HIGH ¹⁰	Obesity (unclassified) increases the risk of severe COVID.
Pneumonia <i>(30-days, communi- ty)</i>	300 per 1000	382 per 1000 (363 to 516)	82 more per 1000 (41 more to 124 more)	Odds Ratio: 1.44 (CI 95% 1.21 to 1.72) ¹¹	35,924 (5)	⊕⊕⊕⊖ MODERATE ¹²	Obesity (unclassified) probably increases the chance of pneumonia due to COVID.
Hospitalisation <i>(30 days, communi- ty)</i>	257 per 1000	340 per 1000 (317 to 362)	83 more per 1000 (60 more to 105 more)	Odds Ratio: 1.31 (CI 95% 1.2 to 1.44) ⁷	515,517 (20)	⊕⊕⊖⊖ LOW ¹³	Obesity (unclassified) may increase the risk of hospitalisation.

*The basis for the **control group absolute risks** from the study(ies) is mean risk across study(ies) unless otherwise stated in comments. The **intervention absolute risk and difference** is based on the risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

GRADE Working UserGroup grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

1. Systematic review. Baseline/comparator control arm of reference used for intervention.
2. Inconsistency: serious. There was a considerable I-squared value. We decided to rate down twice for inconsistency and imprecision. Imprecision: serious. The pooled effect estimate was right below our prespecified threshold of absolute risk difference of 50 in every 1000 COVID patients.
3. Systematic review. Baseline/comparator control arm of reference used for intervention.
4. Inconsistency: serious. Many CIs did not overlap and there was a high I-squared value. The subgroup analysis did not explain the heterogeneity. Publication bias: serious. Asymmetrical funnel plot.
5. Systematic review. Baseline/comparator control arm of reference used for intervention.
6. Inconsistency: serious. The confidence interval of some of the studies did not overlap with those of most included studies/the point estimate of some of the included studies. The magnitude of statistical heterogeneity was high, with an I-squared of about 80%.
7. Systematic review. Baseline/comparator control arm of reference used for intervention.
8. Imprecision: serious. Even though a part of the width of the confidence interval was due to the heterogeneity, the pooled confidence interval spanned rather symmetrically around the absolute risk difference threshold of 50 in 1000.
9. Systematic review. Baseline/comparator control arm of reference used for intervention.
10. No reasons to rate down.
11. Systematic review. Baseline/comparator control arm of reference used for intervention.
12. Imprecision: serious. The lower bound of the confidence interval crossed the prespecified threshold of 50 in 1000 for the absolute risk difference.
13. Inconsistency: serious. Some of the confidence intervals did not overlap with the pooled confidence interval. These different studies require different and conflicting interpretation of their results. Publication bias: serious. An asymmetric funnel plot was observed.

Pneumonia	-	-	-	-	-	-	No studies were found that looked at the impact of continuous obesity on pneumonia.

*The basis for the **control group absolute risks** from the study(ies) is mean risk across study(ies) unless otherwise stated in comments. **The intervention absolute risk and difference** is based on the risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

1. Systematic review. Baseline/comparator control arm of reference used for intervention.
2. No reasons to rate down.
3. Systematic review. Baseline/comparator control arm of reference used for intervention.
4. Imprecision: serious. For this analysis, as the exposure is measured was a continuous variable, we considered no effect as the threshold. However, the limited number of studies and patients compelled us to rate down by one level.
5. Systematic review. Baseline/comparator control arm of reference used for intervention.

6. Inconsistency: serious. The direction of the effect was not consistent between the included studies. Imprecision: serious. Even though the total number of patients in the analysis was considerable, most came from one study.
 7. Systematic review. Baseline/comparator control arm of reference used for intervention.
 8. Risk of Bias: serious. Most of the weight of the analysis was built up of studies at a high risk of bias. Imprecision: serious. The number of participants in the analysis was low.
- Note: BMI - Body Mass Index; CI - Confidence Interval; GRADE - Grading of Recommendations, Assessment, Development and Evaluations

BACKGROUND

1.1. Brief description of the condition and context

In December 2019, a novel coronavirus (SARS-CoV-2) began causing respiratory infections in Wuhan, China. On February 11 2020, the World Health Organization (WHO) classified the virus causing these severe infections as COVID-19 and declared a global pandemic on March 11, 2020 ([Casella 2022](#)). Due to the novelty of COVID-19, researchers around the world are working to understand the prognostic factors that are associated with COVID-19 severity and mortality in order to develop suggestions and guidelines to promote the safety of the public. As of now, various vaccines that are effective against the virus have been introduced ([CDC 2022](#)). In many developed countries such as the United States (US), Canada, and the United Kingdom (UK), a considerable proportion of the population has been vaccinated. However, this has not yet stopped the emergence of new COVID-19 variants of concern ([WHO 2022](#)). In fact, more than 2 years after the beginning of the pandemic, the high number of infections has imposed a crippling burden on healthcare systems around the world. As such, the COVID-19 pandemic continues to utilise a great proportion of healthcare resources without a clear end in sight. Factors that can help in identifying the most vulnerable individuals may assist in better allocating the limited resources. To this end, the goal of our review is to evaluate the independent association between obesity with COVID-19 outcomes.

1.2. Description of the prognostic factor

Obesity is a complex chronic condition associated with numerous predisposing factors such as genetics, social determinants (e.g. income, family eating patterns), environmental conditions (e.g. geographical region, access to transportation), and behavioural factors (e.g. sleep, sedentary lifestyles). The World Health Organization (WHO) defines obesity as a body mass index (BMI) of 30 kg/m² or higher ([WHO 2021](#)). This organisation, further, classifies obesity into three categories with increasing BMI (class I: BMI from 30 to 34.9 kg/m², Class II: BMI from 35 to 39.9 kg/m², and class III: BMI of 40 kg/m² and above). Importantly, the global prevalence of obesity is continually rising ([Inoue 2018](#); [WHO 2021](#); [Wong 2020](#)). In 2016, 13% of adults (aged 18 years and over) had obesity, and this is predicted to rise to 16.1% by 2025 ([WHO 2021](#); [World Obesity 2022](#)). Moreover, obesity is classified by the WHO as a disease, and is also a known prognostic and risk factor for many health conditions, including diabetes, cardiovascular diseases, and cancer ([Ayoub 2019](#); [Cefalu 2015](#); [Früh 2017](#); [Guh 2009](#)). Patients with obesity have been shown to have dysregulated immune responses and chronic low-grade inflammation accompanied by elevated levels of pro-inflammatory cytokines, suggesting that these individuals may be more susceptible to hyperinflammation ([Ritter 2020](#)). Likewise, obesity is associated with reduced pulmonary function, including expiratory reserve volume and functional capacity ([Dietz 2020](#)). Both of these factors may contribute to poorer prognosis from COVID-19 in patients with obesity ([Muscogiuri 2022](#)).

1.3. Health outcomes

Even though the rate of severe adverse events among those who contract the virus remains relatively low, the very contagious nature of the disease has resulted in billions of infections and, consequently, a heavy burden on healthcare systems worldwide ([CDC 2022](#); [Chavez-MacGregor 2021](#); [Schneider 2021](#)). The range

of COVID-19 symptoms varies considerably. About a third of the infected individuals remain asymptomatic, while the other two-thirds could develop symptoms ranging from mild flu-like symptoms to severe respiratory distress syndromes requiring oxygenation, hospitalisation, intensive care unit (ICU) admission, mechanical ventilation, and even death ([Thevarajan 2020](#)). Other serious complications following this infection include cardiac, thromboembolic, neurologic, and inflammatory complications. According to the data available from the United States Center for Disease Control (CDC), amongst the approximately 70 million reported cases of COVID disease in January 2022 in the US, more than 860,000 patients died ([CDC 2022](#)).

The time to recovery following initial symptoms can be quite different based on the patient's age, comorbidities, and severity of disease. Usually, healthy young adults would be symptom-free in as soon as two weeks, while others might suffer from symptoms for much longer ([Sykes 2021](#)).

1.4. Why it is important to do this review

Emerging evidence suggests that obesity increases the severity of COVID-19 and the risk of mortality. Several systematic reviews and meta-analyses have reviewed studies assessing the prognostic value of obesity for COVID-19 severity ([Huang 2020](#); [Hussain 2020](#); [Izcoovich 2020](#); [Popkin 2020](#); [Tamara 2020](#); [Tocalini 2020](#); [Yang 2020](#)). Nonetheless, the studies in these reviews provide conflicting conclusions about the prognostic value of obesity. Some reviews suggest that individuals with obesity are at greater risk for adverse outcomes as compared to individuals with normal weight ([Huang 2020](#); [Izcoovich 2020](#); [Tamara 2020](#); [Yang 2020](#)). In contrast, a review by [Tocalini 2020](#) noted that there is no significant association between obesity and in-ICU COVID-19 mortality. Thus far, however, few of these reviews considered the role of adjusting for covariates in the association between obesity and the COVID-19 adverse outcomes. The observed heterogeneity and the consequent conflicting conclusions amongst the previous primary studies may be related to the extent of adjustment for other covariates. We conducted our systematic review with the aim of clarifying the inconsistency observed across studies by 1) using a more comprehensive search to identify all studies evaluating the association between obesity and adverse outcomes related to COVID-19, and 2) investigating the role of obesity as an independent prognostic factor for COVID-19 mortality and disease severity. Furthermore, to evaluate how reliable the results are and to assess the certainty in the body of evidence, we used the GRADE methodology ([Guyatt 2008](#)). The results of this review may provide evidence for guidelines on the management of COVID-19 patients.

OBJECTIVES

The main objective of this review was to evaluate obesity as an independent prognostic factor for COVID-19 severity and mortality among adult patients in whom infection with the COVID-19 virus is confirmed.

METHODS

3.1 Protocol Registration

We registered the protocol of our systematic review and meta-analysis in the International Prospective Register of Systematic Reviews ([CRD42020190687](#)). This review is reported according to

the Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) guidelines ([Page 2021](#)).

3.2 Criteria for Considering Studies for This Review

3.2.1. Eligibility Criteria

We used the following inclusion criteria for study selection: (i) Study design: case-control, case-series, prospective and retrospective cohort studies, registry data, and secondary analyses of randomised controlled trials; (ii) study participants over 18 years of age who had confirmed COVID-19 infections; (iii) outcomes reported were at least one of the following: mortality, mechanical ventilation, ICU admission, severe COVID, and pneumonia; (iv) statistical analysis included multivariable analyses.

According to the knowledge accumulated to date from the pandemic, children are at minimal risk of contracting the virus and experiencing its adverse outcomes. Therefore, we decided to include only adults above 18 years of age in our review ([Drouin 2021](#)). We specified that if more than 10% of an original study population consists of participants below 18 years of age, the study would be excluded. Furthermore, we only included studies that report the prognostic value of obesity among patients with confirmed COVID-19. However, we did not limit the inclusion to the confirmation method used in the study.

There are numerous methods used for measuring and classifying obesity. The most commonly used indicator is BMI, with further classification of obesity categories based on BMI thresholds. BMI was used to classify obesity into obesity classes I, II, and III. According to the WHO classification, class I obesity includes the BMI range from 30 to 35 kg/m², class II from 35 to 40 kg/m², and class III 40 kg/m² and more ([WHO 2000](#)). Other indicators include waist circumference, waist-to-hip circumference ratio, or other adiposity indicators. We did not exclude the studies that did not use BMI. However, for meta-analyses, we only used obesity categories based on BMI and BMI as a continuous variable. The main reason for this decision was to minimise the degree of expected clinical heterogeneity. Since some countries use lower thresholds for classifying obesity (lower than 30 kg/m²), we accepted the threshold set out in the original studies for our obesity categories. Finally, we included studies that measured and classified obesity prior to the occurrence of our outcomes of interest.

The primary outcomes prespecified in our study protocol were mortality (key outcome), mechanical ventilation, ICU admission, hospitalisation, oxygen requirement, and profound health complications resulting from COVID-19. Due to the availability of resources and practice variations in the administration of oxygen, we decided to omit oxygen requirement as an outcome. We used severe COVID and pneumonia as profound COVID-19 complications because of the availability of data. Furthermore, we included both the binary reporting of hospitalisation and ICU admission, as well as their continuous measures, length of hospitalisation, and ICU admission. We did not place any restriction on the timing of outcome assessment, and included studies with any follow-up period.

This study aimed to further add to the current understanding of the effects of obesity by investigating its independent association with the outcomes. To report independent associations, the most common method that researchers use in observational studies

is to statistically adjust the effect estimate for other possible prognostic factors. Therefore, we decided to only include original studies that at least adjusted their reported obesity effect estimate for another factor. In other words, we only included studies that investigated the (more) independent association between obesity and the outcomes by conducting a multivariable analysis. Due to the large number of included studies, we did not request data that we could not find from the articles from the study authors, for feasibility reasons.

3.3 Search Methods for Identification of Studies

3.3.1. Electronic Databases and Other Sources

Two information specialists developed and conducted systematic searches in the following English and Chinese databases in April 2021 for studies without language or publication status restrictions:

- MEDLINE (via PubMed) (1 Dec 2019 to 23 April 2021)
- Embase (via Ovid) (1 Dec 2019 to 22 April 2021)
- Cochrane COVID-19 Study Register (<https://covid-19.cochrane.org/>) (searched on 23 April 2021)
- COVID-19 Global literature on coronavirus disease (<https://search.bvsalud.org/global-literature-on-novel-coronavirus-2019-ncov/>) (searched on 23 April 2021)
- China Network Knowledge Infrastructure (CNKI) (<http://www.cnki.net/>) (until 22 April 2021)
- Chinese Scientific Journals Database (VIP) (<http://www.cqvip.com/>) (until 22 April 2021)
- Wanfang data (<http://www.wanfangdata.com.cn/index.html>) (until 22 April 2021)
- SinoMed (<http://www.sinomed.ac.cn/>) (until 22 April 2021)

Our detailed search strategy is available as supplemental material in [Appendix 1](#). For greater precision, we searched MEDLINE and Embase from 1 December 2019 onwards as this is the time when COVID-19 became well known. All other sources were searched from inception and without date limits. We elected to employ a Chinese search strategy in four Chinese biomedical databases due to a substantial proportion of the evidence stemming from China at the time of the search.

3.3.2. Other Sources

We also searched the indexed conference abstracts for any additional published papers that were not identified in our electronic search. We included abstracts (otherwise not published) that provided sufficient data for inclusion in our review.

3.3.3. Screening

The results of the systematic searches were screened independently in duplicate according to the eligibility criteria in two stages: title and abstract screening, and full-text screening. We used prespecified question sets for checking the eligibility of studies. These sets were piloted before the screening to ensure a similar understanding among the screeners. In case of any disagreement between the initial screeners, they were instructed to discuss the reasons for their decisions. If a unanimous decision was not reached after the discussion, an adjudicator with expertise in methodology would settle the disagreement. To facilitate the screening process, we used Covidence systematic

review software, Veritas Health Innovation, Melbourne, Australia. Available at www.covidence.org ([Covidience](#)).

3.3.4. Inclusion of non-English language studies

We did not restrict our inclusion to any specific language. When the English text of a paper or abstract was not available, they were screened by authors with adequate knowledge of the relevant language for screening and data extraction.

3.4 Data collection and analysis

We designed an electronic data extraction sheet in Microsoft Excel based on the CHARMS-PF checklist. This checklist is modified by [Riley 2019](#) from the CHARMS checklist for extracting data from prediction model studies ([Moons 2014](#)). The modified checklist is specifically geared toward prognostic factor reviews. Before starting data extraction, we piloted the extraction sheet among the authors to ensure a similar understanding. Data extractors were divided into pairs. Each pair extracted data from the studies in duplicate and independently. Similar to the screening phase, after individual data extraction, disagreements were resolved through pair discussion or third member adjudication, if a unanimous decision was not reached.

For each included study, reviewers extracted the information about study publication, study design and settings, study recruitment and follow-up, study population characteristics, prognostic factor measurement and definition, outcome definition, prognostic factor and outcome prevalence, the unadjusted and adjusted magnitude of effect, adjustment method, adjusted covariates, and missing data. A blank copy of the extraction sheet is provided in the supplementary material as [Appendix 2](#).

3.5. Assessment of Risk of Bias in the Included Studies

Two reviewers independently assessed the risk of bias in the included studies using the Quality in Prognostic Studies (QUIPS) tool ([Hayden 2013](#)). The QUIPS instrument classifies the risk of bias based on six domains: participant selection, attrition, prognostic factor measurement, outcome measurement, study confounding, statistical analysis, and reporting. Each domain can be rated as low, moderate, or high risk of bias. For each study, we rated the overall risk of bias as either high or low. When five QUIPS domains or more were at low risk of bias or only two domains were at moderate risk of bias, we classified the study as at an overall low risk of bias. Otherwise, the study was considered to be at a high overall risk of bias. To facilitate the assessment of the risk of bias, we extracted the suggested information regarding the risk of bias suggested by the CHARMS-PF checklist. We also reported the risk of bias for each study in the forest plots.

3.6. Measures of association

We extracted the magnitude of associations using odds ratios (ORs), hazard ratios (HRs), and relative risks (RRs) for the purpose of meta-analysis. Other measures of association were also gathered for narrative review. We employed validated statistical methods that use each study event rate, the prevalence of prognostic factors, and adjusted effect estimates to calculate the baseline risk of the outcome ([Absolute Risk Calculator 2020](#); [Foroutan 2020b](#)). Consequently, using the mentioned values, HRs and RRs were converted to ORs. The reason to undertake these transformations

was to enable pooling from a wider range of studies including different methodological designs.

3.7. Dealing with Missing Data

We extracted the available information about the missing prognostic factors and outcomes data from the included studies' text. This information was incorporated into the assessment of the risk of bias. Due to the large volume of included studies, we did not ask the original study authors for further information regarding missing data. We also did not apply other methods such as imputations due to the scarcity of sufficient information on the missing data.

3.8. Assessment of Heterogeneity

We explored statistical heterogeneity by visually inspecting forest plots, considering the consistency of point estimates and the extent of overlap in confidence intervals. Even though we calculated statistical measures of heterogeneity such as I^2 and the chi² test significance value, we mostly relied on visual inspection since these measures in meta-analyses of observational studies are usually very large and not helpful. We did not use strict thresholds for the statistical indices. These values along with the visual inspection of the forest plots provided the basis for interpretation of the amount of heterogeneity in a minimally contextualised review setting ([Iorio 2015](#)).

3.9. Assessment of Reporting Deficiencies

In order to assess the risk of bias in reporting the individual studies, we considered the reporting and statistical domain of the QUIPS tool. As for the other domains, the detailed guiding questions directed the final domain judgement. Furthermore, whenever 10 or more studies informed a meta-analysis, we built a funnel plot ([Sterne 2011](#)). The symmetry and distribution of the effect estimates informed our evaluation of publication bias. We did not rely on other tests for the risk of publication bias.

3.10. Data Synthesis

3.10.1 Data Synthesis and Meta-Analysis Approaches

We used [Stata 2015](#) for all analyses. We conducted random-effects model meta-analyses using the Dersimonian and Laird method ([DerSimonian 1986](#)) that pooled the effect estimates from all eligible studies to obtain a summary estimate and confidence interval for each outcome. In addition, for the timing of reported outcomes (other than time-to-event analysis), we decided to consider the closest timing of the reported outcome to 30 days from symptom development. Relevant outcomes included hospitalisation, severe COVID, and pneumonia. Such studies reporting on multiple time points were scarce in this review.

3.10.2. Subgroup Analysis and Investigation of Heterogeneity

We included three subgroup analyses in this review, where possible, which included statistical adjustment set (adjusting for a minimum set of covariates), risk of bias, and statistical reference group for obesity comparison. We specified the subgroup analyses before data extraction. During team discussion, the lack of a strong and unanimous rationale for subgroup effects compelled us to limit the number of subgroup analyses to minimise the chance of observing spurious subgroup effects. For each subgroup

analysis, we used the Instrument for assessing the Credibility of Effect Modification Analyses (ICEMAN) tool to guide us to estimate the credibility of the observed subgroup effect ([Schandlmaier 2020](#)). This tool has been developed for the evaluation of the credibility of a subgroup effect observed in randomised trials or systematic reviews of randomised trials. Even though the tool has not been validated for the systematic reviews of observational studies, each item in the tool is relevant to our review. Furthermore, after discussions, we were unable to add any critical items that were missing from the tool. As we still needed some methods to evaluate the credibility of any observed subgroup effect, we decided to use the concepts and guidance from this tool in addition to the methodologic and clinical expertise of the authors. If moderate or high credibility in the observed subgroup effect emerged after duplicate evaluation, we would report the more appropriate subgroup effect estimate alongside the results from the overall analysis. Furthermore, low or moderate credibility in the subgroup effect was an indicator of possible inconsistency in certainty ratings. The decision to provide both the subgroup and overall effects relies on the fact that the ICEMAN tool has been developed for randomised trials and uncertainty around its performance with observational studies remains.

In the first analysis, we considered the adjustment subgroup. As obesity is closely associated with other comorbidities such as diabetes and cardiovascular diseases, we believe that it is crucial for original studies to at least adjust for some specific variables. Therefore, we decided to prespecify the minimum adjustment set of variables based on the knowledge of COVID-19 disease. Our minimum adjustment set was defined as age, sex, diabetes, hypertension, and cardiovascular disease. This subgroup analysis was performed on all of the mentioned outcomes. Our hypothesis for the direction of this subgroup analysis was that not adjusting for the minimum set would overestimate the magnitude of the effect. It is noteworthy that although the issue of confounders is considered in the statistical analysis domain of the risk of bias evaluation tool, we feel that the importance of the issue in this setting is not sufficiently represented only by a domain of risk of bias. Current evidence strongly supports the role of comorbidities in COVID-19 adverse outcomes ([CDC 2020](#)).

We hypothesised that if there is an association between BMI and COVID outcomes that extends even below the 30 kg/m^2 threshold, considering lower BMI reference ranges would mean that each obesity class magnitude of effect would be estimated larger.

Next, we conducted another subgroup analysis for the effect of the obesity reference group each original study adopted in their regression model. We hypothesised that, if there was an association between BMI and the risk of COVID-19 outcomes that extended even below the 30 kg/m^2 threshold, considering lower BMI reference ranges would mean a larger estimated magnitude of association. The choice of this subgroup analysis was also based on considering a wide range for the comparator group. The results of the analysis could advise the appropriateness of pooling across studies with different reference groups. We considered the group without obesity ($\text{BMI} < 30 \text{ kg/m}^2$) to be the more appropriate reference group. It is important to notice that the association that has been proposed between obesity and COVID adverse outcomes is J-shaped. This means that, potentially, both the very low and very high values of BMI can increase the risk of adverse outcomes from COVID. Therefore, comparing obesity classes to different ranges

of baseline BMI ([Bhaskaran 2018](#)) might affect the magnitude of the effect differently. We believe conducting this subgroup analysis clearly presents how the choice of the reference group influences the magnitude of the effect estimates.

The last subgroup analysis of this review was the overall risk of bias as determined by the QUIPS tool. This subgroup analysis also provided required information for the decision about the overall risk of bias when rating the certainty in the evidence.

3.10.3. Sensitivity Analysis

We only used sensitivity analysis to evaluate the effects of excluding the studies that were believed to drive a considerable portion of overall heterogeneity by having either non-overlapping confidence intervals or noticeably heterogeneous point estimates from the majority of the other studies. We only undertook these sensitivity analyses if the number of excluded studies was below three ([Schandlmaier 2020](#)). The consequent assessment of heterogeneity and the changes in the statistical measures of heterogeneity were considered when assessing the inconsistency of the effect estimates.

We also encountered instances where included studies used $\text{BMI} < 40 \text{ kg/m}^2$ as the reference group for the statistical analyses regarding the association between class III obesity and the outcomes. As this range does not completely overlap the non-obese BMI range, we conducted sensitivity analyses to investigate the effects of removing these studies from the pooled estimates on the interpretation of our results.

3.11 Conclusion and Summary of Findings

For each outcome, we used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) guidance for prognostic factors to assess the certainty of the evidence ([Foroutan 2020a](#)). This methodology guides reviewers to systematically evaluate the certainty of the evidence they have gathered. The certainty levels defined by GRADE include high, moderate, low, and very low. For prognostic factor reviews, the evidence originating from observational studies starts at a high certainty of evidence. Subsequently, this certainty can be rated down or up based on specific grounds. Domains each can rate down the certainty by one or two levels and they include risk of bias in included studies, inconsistency across the effect estimates, imprecision of the pooled estimate, indirectness of the gathered evidence, or risk of publication bias. On the other hand, the situations that allow rating up include a large magnitude of observed effect size, dose-response, and the nature of plausible confounders. In order to rate our certainty in the minimally contextualised framework, we converted the relative effects to absolute risks by using the relative measure of association (OR), the median prevalence of obesity class in patients with COVID-19, and the median of the overall risk of the outcomes across the included studies ([Caussy 2020](#); [Foroutan 2020b](#)). To assess imprecision, we determined an absolute risk increase of 5% to be our threshold for a clinically meaningful prognostic factor (or 50 in 1000 as indicated in the summary of findings tables). When the subgroup analysis for risk of bias showed a significant difference across the high and low risk of bias studies, we used the analysis and conclusions of the meta-analysis of studies at low risk of bias. To prepare the evidence tables presented here we used the Magic online review and guideline management software ([Magic 2022](#)). In the summary of

findings tables, mortality, mechanical ventilation, hospitalisation, ICU admission, pneumonia, and severe COVID were considered as outcomes.

RESULTS

4.1. Description of Studies

4.1.1. Results of the Search

Our searches yielded 10,514 unique records. After the first stage of screening, 495 studies proceeded to full-text screening and 171

were included in the review ([Figure 1](#)). One hundred and forty-nine studies with a total of 12,045,976 participants provided quantitative data for at least one of our meta-analyses. Three manuscripts were in Chinese and were reviewed by a pair of review authors proficient in Chinese. More details of each included study including their set of adjusted covariates can be found in the [Characteristics of included studies](#).

Figure 1. Study flow diagram

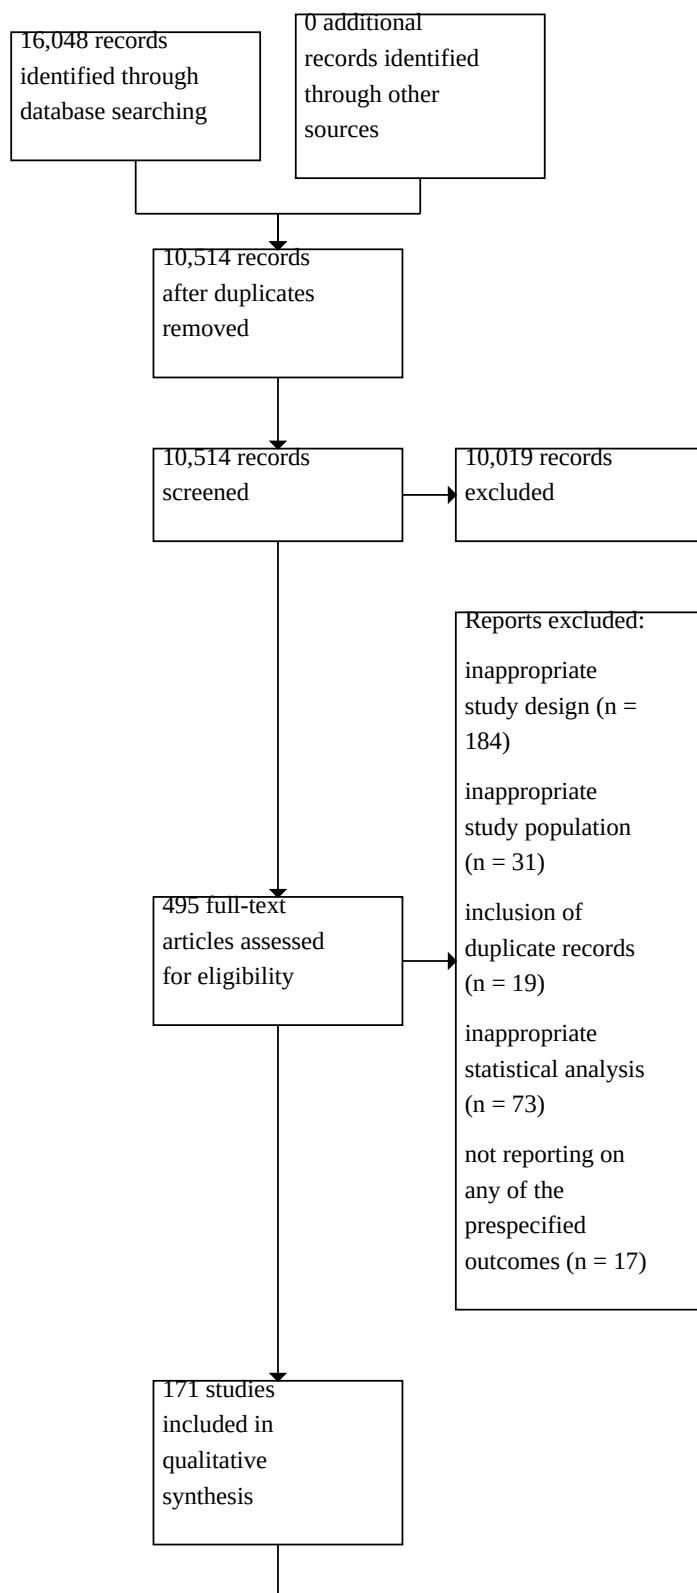

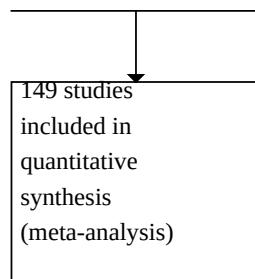

Figure 1. (Continued)

4.1.2. Included studies

Among the 171 included studies, only three studies used a case-control design while 35 and 133 studies were registry data and cohort studies, respectively. Amongst the cohorts, 101 studies were retrospective cohorts and 32 were prospective. More than half of the included studies were conducted in the United States or China ([Table 1](#)). One hundred and fifty-one studies used BMI as an indicator of obesity. Amongst these, 133 used obesity categorisations according to BMI, and 22 used BMI as a continuous variable in their analyses. In terms of the outcomes, 111 studies reported on mortality, 48 on mechanical ventilation, 47 on ICU admission, 34 on hospitalisation, 32 on severe COVID, six on pneumonia, five on length of hospitalisation, two on length of ICU admission, and one on length of mechanical ventilation. As per our inclusion criteria, all these studies adjusted for at least one covariate in addition to obesity. A table of characteristics of included studies provides the full details of each included study including the set of adjusted covariates ([Characteristics of included studies](#)).

4.1.3. Excluded Studies

In total, 324 studies were excluded after reviewing full texts. Reasons for this include inappropriate study design ($n = 184$), inappropriate study population ($n = 31$), the inclusion of duplicate

records ($n = 19$), inappropriate statistical analysis ($n = 73$, only univariate analysis), and not reporting on any of the prespecified outcomes ($n = 17$). We have provided examples of eight key studies that were excluded in [Characteristics of excluded studies](#).

4.1.4. Risk of Bias in Included Studies

We used the QUIPS tool to assess the risk of bias in the included studies. We assigned scores of 0, 1, and 2 to each domain at a low, medium, and high risk of bias respectively. The sum of domain scores of more than 2 indicated the studies were at a high risk of bias. We judged 54% of all reported outcomes at low risk of bias ([Risk of Bias Assessments](#)). Regarding the ICU admission, most of the studies had low risk of bias ($n = 27$, 57%). Most of the studies that measured mortality, hospitalisation and mechanical ventilation had low risk of bias (56%, 57%, and 52%, respectively). We found one study that measured the length of mechanical ventilation, which we judged to have a low risk of bias. For pneumonia and length of ICU stay, 50% of studies had a low risk of bias. However, regarding the length of hospitalisation and severe Covid-19 outcomes, most of the studies had a high risk of bias (60% and 58%, respectively). [Table 2](#), [Table 3](#), [Figure 2](#), and [Figure 3](#) summarise the judgements about the overall risk of bias and risk of bias domains judgments for each outcome. We used funnel plots to investigate the risk of publication bias for comparisons that included more than 10 studies ([Appendix 3](#)).

4.2. Results of the Synthesis

Below, we provide a summary of the results of all the outcomes of interest to the review. Detailed findings for the outcomes we considered to be of greater importance to the patients (mortality, mechanical ventilation, and ICU admission) are presented in this section, with brief interpretations of the findings of the remaining outcomes. Further details on the findings for the remaining outcomes are detailed in the Summary of findings tables and forest plots.

4.2.1. Mortality

In total, 105 studies reported effect sizes on the association between obesity and mortality. The majority of the studies reported at least one association ($n = 61$) between unclassified obesity and mortality due to COVID-19. Further, we were able to extract 15, 12, and 23 reported effect estimates for obesity class I, II, and III meta-analyses, respectively.

4.2.1.1. Obesity Class I

We included 15 studies to estimate a pooled effect estimate for the association between obesity class I (versus patients without obesity) and COVID-19 mortality. These studies included 335,209 participants in total. Nine of the studies were judged to be at low overall risk of bias. Synthesis of the results of these studies revealed that patients within class I obesity did not have a higher odds of mortality due to COVID (pooled OR 1.04, 95% CI 0.94 to 1.16, $I^2 = 76.1\%$, Figures S1-S3) compared to patients without obesity. We incorporated the baseline risk of death from the included studies to transform this relative effect into an absolute risk difference (baseline risk: 180/1000). We concluded that when comparing 1000 obesity class I COVID-19 patients to the ones without obesity, six more patients die amongst every 1000 obesity class I patients with COVID-19 compared to COVID-19 patients without obesity (95% CI from 9 fewer to 23 more, GRADE certainty in the evidence: High, Summary of findings 1).

Comparing this finding to the minimally contextualised threshold of 50 patients in every 1000, we believe obesity class I makes little to no difference to the risk of mortality from COVID-19. We also conducted three subgroup analyses. First, we compared

effect estimates from studies that adjusted for at least age, sex, DM (diabetes mellitus), HTN (hypertension), and cardiovascular diseases with those from studies that did not (Figure S1). Next, we compared effect estimates between studies that used different BMI ranges as their reference group (Figure S2) and between studies with high and low overall risk of bias (Figure S3). Our evaluation of these subgroup effects, as guided by the ICEMAN tool, did not suggest any credible difference.

4.2.1.2. Obesity Class II

Eleven studies with 317,925 participants in total contributed to the pooled effect size for the association between COVID-19 death and obesity class II. Six of the studies were at a low overall risk of bias. Ten studies used the normal BMI range (18.5 to 24.9 kg/m²) as the reference regression analysis group, one study used the non-obese range (BMI < 30 kg/m²), and the last study did not specify its reference range. Our meta-analysis indicated that obesity class II based on BMI can introduce 1.16 times higher odds of mortality compared to having a BMI between 18.5 and 24.9 kg/m² (pooled OR 1.16, 95% CI 0.99 to 1.36, $I^2 = 83.3\%$, Figures S4-S6), but since the 95% CI includes 1, we cannot infer that the patients with obesity class II have a higher risk of mortality compared to the normal BMI patients. After considering the baseline risk of 180/1000 for COVID-19 mortality in the included studies, this result translates into 23 more patients (95% CI from 1 fewer to 50 more, GRADE certainty in the evidence: High, Summary of findings 2) dying amongst every 1000 obesity class II patients with COVID-19 compared to COVID-19 patients without obesity.

Therefore, we believe that obesity class II makes little to no difference to the risk of mortality from COVID-19 when considering a minimally important difference threshold of 50 more deaths in every 1000 patients. Similar to the previous class, our three subgroup analyses did not find any credible subgroup effects (Figures S4-S6).

4.2.1.3. Obesity Class III

We pooled the effect sizes from 19 studies with a total of 354,967 participants. Fourteen studies were at a low overall risk of bias. Similarly, 15 studies adjusted their effect estimate for at least age,

sex, DM, HTN, and cardiovascular diseases. Most of the studies used the normal or non-obese BMI range as the reference group ($n = 15$). However, four studies did not specify what reference group they reported their effect estimate against and one study used any BMI less than 40 kg/m^2 as the comparator (Bennett 2021). The results of the meta-analysis indicate that COVID-19 patients with class III obesity, as compared to patients with $\text{BMI} < 30 \text{ kg/m}^2$ (without obesity), have approximately 1.6 times higher odds of mortality (pooled OR 1.67, 95%CI 1.39 to 2.00, $I^2 = 85.6\%$, Figures S7-S9). Applying this to the baseline risk of mortality (180/1000 from the included studies) translates to 88 more deaths (95% CI from 54 more to 125 more, GRADE certainty in the evidence: Low, [Summary of findings 3](#)) amongst every 1000 COVID-19 patients with class III obesity compared to patients with $\text{BMI} < 30 \text{ kg/m}^2$.

Although the confidence interval of the pooled effect size surpasses the minimally contextualised threshold of 50 in 1000, we decided to rate down the certainty in the evidence because of inconsistency and the risk of publication bias ([Summary of findings 3](#)). The judgement about possible publication bias was based on the asymmetry in the funnel plot ([Funnel Plots](#)). Moreover, heterogeneity and considerable visual inconsistency among reported effect estimates with various possible interpretations informed the decision about penalising the certainty of evidence in the inconsistency domain. Therefore, we believe that obesity class III may increase the risk of mortality from COVID-19.

The evidence suggests that obesity class III may increase the risk of mortality among COVID-19 patients compared to those with $\text{BMI} < 30 \text{ kg/m}^2$. We conducted three subgroup analyses on adjustment covariates, regression reference group, and risk of bias (Figures S7-S9). Our evaluation of these analyses did not suggest any credible subgroup effect. Furthermore, as the regression analysis reference group in Bennett 2021 included other obesity classes, we carried out a sensitivity analysis to investigate the effect of excluding this study from the meta-analysis. The result of this analysis did not indicate any change in the interpretation of the results (pooled OR 1.61, 95% CI 1.34 to 1.92, 18 studies, 335,178 participants, $I^2 = 84.4\%$).

4.2.1.4. Obesity (Unclassified)

We also pooled the effect estimates from the studies that reported on the association between mortality among COVID-19 patients and obesity without further classifying it ($\text{BMI} \geq 30 \text{ kg/m}^2$). This meta-analysis included 60 effect estimates from 54 studies with a total of 1,307,516 participants. Thirty studies were at low overall risk of bias. Twenty-two studies used $\text{BMI} < 30 \text{ kg/m}^2$, nine studies BMI between 18.5 and 24.9 kg/m^2 , and 23 studies unspecified range as the reference group. The results suggest that patients with obesity with COVID-19, compared to the patients without ($\text{BMI} < 30 \text{ kg/m}^2$), demonstrate a higher odds of mortality (pooled OR 1.35, 95% CI 1.28 to 1.42, $I^2 = 70.7\%$, Figures S10-S12). Similar to the previous categories, we translated this relative measure to an absolute risk difference by incorporating the baseline risk of mortality in COVID-19 patients (180/1000) from the included studies. We concluded that, in every 1000 unclassified COVID-19 patients with obesity, compared to 1000 COVID-19 patients without, on average 49 more patients die (95% CI from 39 more to 58 more, GRADE certainty in the evidence: Low, [Summary of findings 4](#)).

We decided to rate down the certainty in this evidence for inconsistency and imprecision. The pooled confidence cut through the prespecified minimally important threshold. In addition, the effect estimates were visually inconsistent across the threshold. This, in our belief, cannot justify the confidence interval crossing over the threshold. Therefore, we believe that unclassified obesity may make little to no difference to the risk of mortality. Notice that our point estimate of the effect size lies exactly below the 50 in 1000 threshold for an important difference. The results of subgroup analyses could not convince us of any credible differences among subgroups (Figures S10-S12).

4.2.1.5. Units Change in BMI

Ten studies reported effect estimates considering BMI as a continuous independent variable. These studies had 6,937,151 participants. However, 6,910,695 participants were from one study. Six of the studies were at low risk of bias and six adjusted the effect estimate for at least age, sex, DM, HTN, and cardiovascular diseases. We calculated the effect estimates from each study corresponding to every 5 units increase in BMI using appropriate logarithmic transformations. The analysis revealed that increasing BMI corresponds to higher odds for mortality among COVID-19 patients (for every 5 units increase in BMI: pooled OR 1.16, 95% CI 1.08 to 1.24, $I^2 = 94.4\%$, Figures S13-S14).

We calculated that considering the baseline mortality risk of 180/1000, on average 23 more (95% CI from 12 more to 34 more, GRADE certainty in the evidence: High, [Summary of findings 5](#)) out of every 1000 COVID patients die compared to 1000 with 5 units lower BMI. Since this interpretation of results is dealing with a continuous exposure variable, we avoided the use of the previous threshold (defined for binary interpretations of exposure) and considered a difference of zero as the threshold. We, therefore, concluded that every 5-unit increase in BMI increases the risk of mortality among patients with COVID-19 infection.

4.2.2. Mechanical Ventilation

We were able to extract 81 effect estimates from 46 unique studies that associated some measure of obesity with the incidence of mechanical ventilation after contracting the COVID-19 virus. Similar to mortality, most studies ($n = 22$) used unclassified obesity ($\text{BMI} \geq 30 \text{ kg/m}^2$). This was followed by obesity class III ($n = 12$), class I ($n = 10$), class II and III aggregate ($n = 9$), and class II ($n = 6$).

4.2.2.1. Obesity Class I

We included 10 studies in the meta-analysis on the association between obesity class I and the need for mechanical ventilation with a total of 187,895 participants. The risk of bias assessment indicated that six of these studies have a low overall risk of bias. All studies compared this obesity class to normal BMI ($\text{BMI} 18.5$ to 24.9 kg/m^2) except one that did not indicate its analysis reference group. In terms of adjustment, eight studies adjusted their effect estimate for at least age, sex, DM, HTN, and cardiovascular diseases. The meta-analysis revealed that COVID-19 patients with class I obesity are at higher odds of needing mechanical ventilation compared to those within the normal BMI range of 18.5 to 24.9 kg/m^2 (pooled OR 1.38, 95% CI 1.20 to 1.59, $I^2 = 62.1\%$, Figures S15-S17).

The calculations estimated that the baseline risk of the need for mechanical ventilation is 198 in every 1000 COVID-19 infections. We applied the pooled OR to this risk and found that in every

1000 obesity class I patients with COVID-19, 56 more people (95% CI from 31 more to 84 more, GRADE certainty in the evidence: Moderate, [Summary of findings 1](#)) need mechanical ventilation compared to BMI between 18.5 to 24.9 kg/m². We rated down the certainty in this evidence since the pooled confidence interval crossed the prespecified minimal important threshold of 50 in 1000. Therefore, we concluded that obesity class I, compared to the normal BMI range, probably increases the risk of mechanical ventilation. Our subgroup analyses did not point to any credible difference between the subgroups ([Figures S15-S17](#)).

4.2.2.2. Obesity Class II

A total of 171,149 participants from six studies contributed to estimating the effects of class II obesity on mechanical ventilation. Half of the studies were at low overall risk of bias. Similar to the previous class, only one study did not specify its reference group while others used the normal BMI range of 18.5 to 24.9 kg/m². The synthesis of the results of the included studies revealed that obesity class II COVID-19 patients have higher odds of needing mechanical ventilation (pooled OR 1.67, 95% CI 1.42 to 1.96, $I^2 = 61.7\%$, [Figures S18-S20](#)).

This relative effect means that considering the baseline risk (198/1000), 94 more (95% CI from 62 more to 128 more, GRADE certainty in the evidence: High, [Summary of findings 2](#)) patients among every 1000 with COVID-19 need mechanical ventilation when categorised as having class II obesity compared to the normal BMI range. Therefore, obesity class II increases the risk of requiring mechanical ventilation among COVID-19 patients. The subgroup analyses did not demonstrate any considerable differences across the groups ([Figures S18-S20](#)).

4.2.2.3. Obesity Class III

Twelve studies with a total of 174,520 participants reported on the prognostic effects of class III obesity on mechanical ventilation. Five studies were at a low overall risk of bias. Reference groups in these studies included patients without obesity, normal BMI range, BMI less than 40, and unspecified. The analysis suggested that obesity class III, compared to the patients without obesity (BMI < 30 kg/m²), increases the odds of requiring mechanical ventilation among COVID-19 (pooled OR 2.17, 95% CI 1.59 to 2.97, $I^2 = 95.0\%$, [Figures S21-S23](#)).

This means that with the baseline risk of 198/1000, in every 1000 COVID-19 patients 151 more with obesity class III (95% CI from 84 more to 225 more, GRADE certainty in the evidence: High, [Summary of findings 3](#)) require mechanical ventilation compared to those without obesity. Therefore, we believe that obesity class III increases the risk of mechanical ventilation among COVID-19 patients. We also conducted a sensitivity analysis to evaluate the effects of removing studies with a BMI less than 40 as the reference for our interpretation. This analysis showed that removing these studies does not alter our findings (pooled OR 2.12, 95% CI 1.50 to 2.98, 10 studies, 173,679 participants, $I^2 = 95.9\%$). Further, the subgroup analyses did not yield any credible subgroup effects ([Figures S21-S23](#)).

4.2.2.4. Obesity (Unclassified)

We also conducted a meta-analysis of effect estimates from studies that reported the association between mechanical ventilation and obesity without further classifying it (BMI ≥ 30 kg/m²). Pooling

information from 21 studies with a total of 62,348 participants showed that COVID-19 patients with obesity have higher odds of needing mechanical ventilation compared to those without obesity (BMI < 30 kg/m²) (pooled OR 1.69, 95% CI 1.44 to 1.99, $I^2 = 93.9\%$, [Figures S24-S26](#)).

Applying this relative measure to the baseline risk indicates that, in every 1000 patients with obesity, relative to those patients without, 96 more (95% CI from 64 more to 131 more, GRADE certainty in the evidence: Low) patients would need mechanical ventilation. We rated down the certainty in the evidence due to inconsistency and publication bias. Therefore, we can conclude that obesity may increase the risk of mechanical ventilation among COVID-19 patients. The subgroup analyses did not show any credible subgroup effects ([Figures S24-S26](#)).

4.2.2.5. Units Change in BMI

Two studies with 13,527 participants investigated BMI as a continuous prognostic factor for mechanical ventilation. One of these was at low overall risk of bias. COVID-19 infected patients with higher BMIs, on average, had higher odds of requiring mechanical ventilation (for every 5 units increase in BMI: pooled OR 1.28, 95% CI 1.24 to 1.31, $I^2 = 0.0\%$, [Figure S27](#)). This translates into 42 more per 1000 (95% CI from 36 more to 46 more, GRADE certainty in the evidence: Moderate, [Summary of findings 5](#)). We rated down the certainty in the evidence due to imprecision as the number of studies and participants in the analysis was limited. Therefore, we believe that increasing BMI probably increases the risk of requiring mechanical ventilation among COVID-19 patients. The subgroup analyses did not show any subgroup effect.

4.2.3. ICU admission

We extracted 63 effect estimates on the association between obesity and ICU admission. These were reported by 45 unique studies. Unclassified obesity (BMI ≥ 30 kg/m²), class I obesity, class II obesity, class III obesity, and continuous BMI accounted for 21, 7, 4, 7, and 5 effect estimates, respectively.

4.2.3.1. Obesity Class I

For obesity class I, seven studies were included. In the analysis of the effects of obesity class I on ICU admission, seven studies with a total of 162,741 participants provided information. Just more than half of the studies were at low overall risk of bias ($n = 4$), and studies at a high risk of bias accounted for more than 40% of the total pooling weight and 90% of participants. Both patients without obesity (BMI < 30 kg/m², $n = 2$) and normal BMI ranges (18.5 \leq BMI < 25 kg/m², $n = 5$) served as the reference group in the included studies. On average, COVID-19 patients with class I obesity had higher odds of being admitted to ICU compared to those patients without obesity (pooled OR 1.36, 95% CI 1.06 to 1.75, $I^2 = 82.4\%$, [Figures S28-S30](#)).

We calculated the baseline risk of ICU admission in the included studies (208/1000). Combining this with the pooled OR revealed that in every 1000 COVID-19 patients with class I obesity compared to patients without obesity, 55 more (95% CI from 10 more to 107 more, GRADE certainty in the evidence: Moderate, [Summary of findings 1](#)) patients were admitted to ICU. We rated down (by one level) the certainty in the evidence for imprecision and risk of bias combined as the confidence interval crossed the minimally contextualised threshold of 50 in 1000 and the high risk of bias

studies accounted for nearly half of the total weight of the pooled analysis. Therefore, obesity class I probably increases the risk of ICU admission. The subgroup analyses for this class of obesity did not demonstrate a credible subgroup effect ([Figures S28-S30](#)). It is noteworthy that, however, the pooled effect size from studies with a reference group with normal range of BMI was smaller than that of studies with a reference group with a non-obese range of BMI.

4.2.3.2. Obesity Class II

For obesity class II, four studies were included. We pooled the effect estimates from four studies with 157,665 patients that reported on the effects of obesity class II on ICU admission. Only one of the studies, contributing 30% of the total weight of the pooled analysis, was at low risk of bias. All of the studies used the normal BMI range ($18.5 \leq \text{BMI} < 25 \text{ kg/m}^2$) as their statistical analysis reference group. Patients with class II obesity, compared to the normal range of BMI, had almost similar odds of ICU admission (pooled OR 1.02, 95% CI 0.90 to 1.15, $I^2 = 35.9\%$, [Figures S31-S33](#)).

After applying the baseline risk (208/1000), we found that three more (95% CI from 17 fewer to 24 more, GRADE certainty in the evidence: Low, [Summary of findings 2](#)) out of 1000 COVID-19 patients with obesity class II, compared to normal BMI range, were admitted to ICU out of every 1000 patients. Rating down the certainty in the evidence was due to the very serious risk of bias in the included studies. Therefore, we concluded from this result that obesity class II may have little to no difference in the risk of ICU admission.

4.2.3.3. Obesity Class III

Seven studies reported the difference between patients with a normal BMI and patients with class III obesity. For the effects of this class of obesity on ICU admission, we found a subgroup difference when comparing studies that adjusted the effect estimate for at least age, sex, DM, HTN, and cardiovascular diseases ([Figure S34](#)). As mentioned in the Methods section, we considered the guidance by the ICEMAN tool as a general framework for the evaluation of the subgroup-effect credibility. Because the subgroup effect was credible, we conducted a meta-analysis that only included studies that adjusted for the minimum set of DM, HTN, cardiovascular disease, age, and sex. For this reason, we present the results of both the overall meta-analysis and the sensitivity analysis including only the studies adjusting for a minimum set of covariates in the following text and [Summary of findings 3](#).

For the overall group of studies, seven studies contributed to the meta-analysis with a total of 159,691 participants. The four studies that were at a high risk of bias in this analysis contributed about 56% of the weight of the total pooled analysis. While two studies considered a BMI less than 40 kg/m^2 as the reference, four considered the normal BMI range ($18.5 \text{ to } 24.9 \text{ kg/m}^2$), and one did not specify their reference group. The analysis suggests that patients with morbid obesity have a higher odds of admission to the ICU (pooled OR 2.26, 95% CI 1.41 to 3.63, 7 studies, 159,691 participants, $I^2 = 94.3\%$, [Figures S35-S36](#)) compared to the normal BMI range.

This finding can be expressed as an absolute risk difference after incorporating the baseline risk of 208/1000. When comparing 1000 COVID-19 patients with class III obesity to 1000 who are not suffering from morbid obesity, 164 more patients are admitted to

ICU (95% CI from 62 more to 280 more, GRADE certainty in the evidence: Low, [Summary of findings 3](#)). As mentioned earlier, these results should be cautiously interpreted alongside the results from the minimally adjusted subgroup.

In the sensitivity analysis including only the studies adjusting for a minimum set of covariates, we included three studies with 155,405 participants. Only one study with a weight of about 40% of the total pooled effect was at low risk of bias. Also, one study used BMI less than 40 as the reference group ([Suleyman 2020](#)), while others used the normal BMI range ($18.5 \leq \text{BMI} < 25 \text{ kg/m}^2$). We found that, on average, COVID-19 patients with obesity class III had an OR of 1.20 (95% CI 0.97 to 1.49, $I^2 = 74.7\%$, [Figures S37-S38](#)) of requiring ICU admission compared to normal range BMI.

We translated this finding to an absolute risk difference by incorporating the baseline risk of ICU admission from included studies (208/1000). In every 1000 COVID-19 patients with obesity class III, 32 more (95% CI from 5 fewer to 73 more, GRADE certainty in the evidence: Moderate, [Summary of findings 3](#)) patients would get admitted to ICU compared to those having a BMI range between 18.5 and 24.9 kg/m^2 . Therefore, obesity class III probably makes little to no difference to the risk of ICU admission when adjusted for DM, HTN, cardiovascular diseases, age, and sex. A sensitivity analysis to investigate the effects of removing the study using a BMI less than 40 as the reference group demonstrated no change in the interpretation of the results or the certainty in the evidence (pooled OR 1.06, 95% CI 1.01 to 1.11, 2 studies, 155,050 participants, $I^2 = 0.0\%$).

4.2.3.4. Obesity (Unclassified)

Twenty one-studies investigated the association between obesity and ICU admission without specification of obesity class ($\text{BMI} > 30 \text{ kg/m}^2$). These studies included 69,147 participants and 12 of them were at a low overall risk of bias. The reference groups used in these 21 studies included normal BMI range ($18.5 \leq \text{BMI} < 25 \text{ kg/m}^2$, $n = 3$), non-obese BMI range ($\text{BMI} < 30 \text{ kg/m}^2$, $n = 8$), and unspecified ($n = 10$). On average, COVID-19 patients with obesity had an almost twice larger odds of ICU admission (pooled OR 1.86, 95% CI 1.56 to 2.21, $I^2 = 88.4\%$, [Figures S39-S41](#)) compared to those patients without obesity.

By applying the baseline risk of 208/1000, this can be expressed as 123 more (95% CI from 84 more to 164 more, GRADE certainty in the evidence: Moderate, [Summary of findings 4](#)) people would get admitted to ICU amongst every 1000 patients with obesity compared to those without ($\text{BMI} < 30 \text{ kg/m}^2$). Therefore, after comparing this absolute risk difference to the threshold of 50 in every 1000, we conclude that obesity (without further classification) probably increases the risk of ICU admission.

4.2.3.5. Units Change in BMI

No studies were found that looked at the impact of continuous obesity on ICU admission.

4.2.4. Hospitalisation

4.2.4.1. Obesity Class I

Analyses provided moderate-certainty evidence that patients with class I obesity probably have a similar risk of hospitalisation compared to patients without obesity ($\text{BMI} < 30 \text{ kg/m}^2$) with no

evidence of credible subgroup effects (pooled OR 0.96, 95% CI 0.82 to 1.14, 5 studies, 515,115 participants, $I^2 = 96.8\%$, [Summary of findings 1; Figures S42-S44](#)).

4.2.4.2. Obesity Class II

Analyses provided moderate-certainty evidence that patients with class I and II obesity probably have a similar risk of hospitalisation compared to patients without obesity ($BMI < 30 \text{ kg/m}^2$) with no evidence of credible subgroup effects (pooled class II: OR = 1.04, 95% CI 0.90 to 1.2, 3 studies, 293,707 participants, $I^2 = 94.9\%$, [Summary of findings 2; Figures S45-S46](#)).

4.2.4.3. Obesity Class III

On the contrary to classes I and II obesity, patients with class III obesity (low certainty of evidence, [Summary of findings 3](#)) may have an increased risk of hospitalisation, when considering studies that adjusted for at least age, sex, DM, HTN, and cardiovascular diseases (pooled class III: OR = 1.35, 95% CI 1.19 to 1.52, 3 studies, 293,004 participants, $I^2 = 91.4\%$, [Summary of findings 3; Figures S47-S51](#)). The analyses that considered all the studies suggested that obesity class III may be an important factor increasing the risk of hospitalisation (pooled class III: OR = 1.77, 95% CI 1.40 to 2.26, 7 studies, 747,176 participants, $I^2 = 95.4\%$, low certainty-evidence, [Summary of findings 3; Figures S47-S51](#)).

4.2.4.4. Obesity (Unclassified)

Patients with unclassified obesity (moderate certainty of evidence, [Summary of findings 4](#)) probably have an increased risk of hospitalisation, when considering studies that adjusted for at least age, sex, DM, HTN, and cardiovascular diseases (pooled obesity (unclassified): OR 1.31, 95% CI 1.20 to 1.44, 14 studies, 510,405 participants, $I^2 = 91.4\%$, [Figures S52-S56](#)). The analyses that considered all the studies suggested that unclassified obesity may be an important factor increasing the risk of hospitalisation (pooled obesity (unclassified): OR 1.49, 95% CI 1.34 to 1.64, 20 studies, 515,517 participants, $I^2 = 82.1\%$, low certainty-evidence, [Summary of findings 4; Figures S52-S56](#)).

4.2.4.5. Units Change in BMI

Also, low-certainty evidence suggests that every 5 units increase in BMI may also increase this risk (pooled OR, 1.17, 95% CI 1.05 to 1.31, 3 studies, 6,911,600 participants, $I^2 = 62.9\%$, [Summary of findings 5; Figures S57-S58](#)).

4.2.5. Severe COVID disease

4.2.5.1. Obesity Class I

Analyses provided low-certainty evidence that patients with class I obesity may have an increased risk of severe COVID compared to patients without ($BMI < 30 \text{ kg/m}^2$), with no evidence of credible subgroup effects (pooled class I: OR = 1.48, 95% CI 1.16 to 1.87, 3 studies, 1040 participants, $I^2 = 0.0\%$, [Summary of findings 1; Figures S59-S61](#)).

4.2.5.2. Obesity Class II

No studies were found that looked at the impact of obesity class II on severe COVID-19 disease.

4.2.5.3. Obesity Class III

No studies were found that looked at the impact of obesity class III on severe COVID-19 disease.

4.2.5.4. Obesity (Unclassified)

As to the association between unclassified obesity and this outcome, high-certainty evidence suggests that COVID-19 patients with obesity, compared to patients without ($BMI < 30 \text{ kg/m}^2$), are at an increased risk of developing severe disease (pooled OR = 1.94, 95% CI 1.62 to 2.32, 19 studies, 878,804 participants, $I^2 = 69.5\%$, [Summary of findings 4; Figures S62-S64](#)).

4.2.5.5. Units Change in BMI

Analyses provided low-certainty evidence that patients with higher BMI (continuous) may have an increased risk of severe COVID-19 compared to patients without ($BMI < 30 \text{ kg/m}^2$), with no evidence of credible subgroup effects (pooled BMI per 5 kg/m^2 increase: OR 1.94, 95% CI 1.39 to 2.7, 5 studies, 1041 participants, $I^2 = 35.1\%$, [Summary of findings 5; Figures S65-S66](#)).

4.2.6. Pneumonia

4.2.6.1. Obesity Class I

No studies were found that looked at the impact of obesity class I on pneumonia due to COVID-19 disease.

4.2.6.2. Obesity Class II

No studies were found that looked at the impact of obesity class II on pneumonia due to COVID-19 disease.

4.2.6.4. Obesity (Unclassified)

Analysis of moderate-certainty evidence suggests that patients with obesity (unclassified), compared to those with non-obesity ($BMI < 30 \text{ kg/m}^2$) probably have an increased risk of pneumonia due to COVID-19 (pooled OR = 1.44, 95% CI 1.21 to 1.72, 5 studies, 35,924 participants, $I^2 = 81.4\%$, [Summary of findings 4; Figure S67](#)).

4.2.6.5. Units Change in BMI

No studies were found that looked at the impact of the increase in BMI on pneumonia due to COVID-19 disease.

4.3. Other Outcomes

We also identified other studies that reported on length of hospitalisation, length of ICU admission, and length of mechanical ventilation. All but one of these studies reported adjusted hazard ratios by considering hospital discharge, ICU discharge, or extubation as time-to-event outcomes. [Biscarini 2020](#), in contrast, considered the length of hospitalisation a continuous outcome and reported a beta coefficient (slope) for the adjusted effects of obesity.

[Hur 2020](#) included 564 patients hospitalised with COVID-19 and analysed the data for a final cohort of 486 patients of whom a total of 138 patients were intubated during the course of the study. The study considered the time from intubation to extubation with censoring patients at death or those intubated at the time of the final follow-up. This adjusted analysis for age, sex, race, HTN, and smoking indicated an HR of 0.53 (95% CI 0.32 to 0.90) for obesity class I and II combined ($BMI 30$ to 40 kg/m^2) and an HR

of 0.40 (95% CI 0.19 to 0.83) for obesity class III. These were both compared to the reference group of the patients without obesity. These findings suggest that COVID-19 patients without obesity have a higher instantaneous chance of extubation at any time during their period of intubation.

Another study by [Parikh 2020](#) reported on time from ICU admission to ICU discharge among 160 COVID-19 patients who were admitted to ICU. After adjusting for age, sex, and a history of asthma, the study reported an adjusted HR of 0.9 (95% CI 0.5 to 1.7) for ICU discharge and an adjusted HR of 1.2 (95% CI 0.7 to 2.2) for hospital discharge when comparing patients with obesity to those without. While the point estimates may indicate that obesity lowers the instantaneous chance of ICU discharge but increases the same chance for hospital discharge after ICU admission, the wide confidence intervals include the no-effect line.

Regarding the time from hospital admission to discharge, [Hu 2020](#) and [Van Zelst 2020](#) conducted Cox proportional hazard regression analysis, compared to the linear regression by [Biscarini 2020](#). This latter study reported that the analysis of 427 patients suggests that patients with obesity, compared to those without, have an average increase of 1.19 days (95% CI -1.88 to 4.26) in the length of hospital stay when adjusted for some covariates like age, sex, and some comorbidities. The study by [Hu 2020](#) included 58 admitted patients with mild COVID-19 from whom those with obesity had an adjusted HR of 0.83 (P value for trend = 0.001) for hospital discharge. The other study with a similar analysis, by [Van Zelst 2020](#), analysed the data for 79 COVID-19-positive patients, of whom 74 were admitted to the hospital. After adjustment for age, sex, and presence of metabolic syndrome, this study reported a hospital discharge adjusted HR of 0.97 (95% CI 0.92 to 1.01) when comparing patients with obesity to those without.

DISCUSSION

5.1. Summary of main results

Our review investigated the prognostic effects of obesity on adverse COVID-19 outcomes. We located and evaluated available evidence about patient-important outcomes such as mortality, mechanical ventilation, and ICU admission. We also investigated the effects of obesity on hospitalisations, severe disease, and pneumonia due to COVID-19.

High-certainty evidence suggested that obesity class I and II does not meet a minimal threshold of 5% absolute risk increase for mortality. On the other hand, our analysis for class III obesity showed that the effect of this class exceeds this threshold, although this is low-certainty evidence. A closer look at these observed effect sizes, interestingly, reveals that a dose-response relationship exists. The absolute mortality risk difference (relative to patients without obesity) for COVID-19 patients with obesity indicates a rise from 0.06% more to 8.8%, from class I to class III, respectively. This suggests that obesity possibly plays a role in increasing the risk of mortality, even though the milder two classes impose less than a 5% risk increase, which we considered the threshold of an **important** prognostic factor. This finding is also in line with the high-certainty of evidence that exhibited an increased mortality risk for every five units of BMI increase. Our best estimate is that every five units of BMI increase inflates mortality risk by more than 2%.

Coherently for all obesity classes, the evidence points toward an increased risk of mechanical ventilation among patients with obesity. The certainty of the evidence for classes II and III is high while for class I is moderate. Similar to mortality, we observed a dose-response relationship which further supports the conclusion that obesity is associated with an increased risk for this outcome. The amount of this risk increase ranges from more than 5% to 15% for different obesity classes. Findings regarding every 5 units increase in BMI and unclassified obesity was also aligned with this elevated risk, however, with moderate and low certainty of evidence. We interpret these findings to indicate that all obesity classes are important prognostic factors for the need for mechanical ventilation among COVID-19 patients.

In contrast to mortality and mechanical ventilation, the observed effects on ICU admission were not congruent across obesity classes. We observed the highest risk of ICU admission with an absolute risk increase of 5.5% from moderate-quality evidence amongst participants with class I obesity. This suggests that this obesity class is probably an important prognostic factor. However, for obesity class II and class III, the absolute increase in ICU admission risk was only 0.03% and 2.3% from low-quality and moderate-quality evidence, respectively. Further adding to this incongruity, the low-quality evidence from studies investigating unclassified obesity suggests a 12.3% increase in ICU admission risk. Therefore, we believe that interpretation of our findings for ICU admission should be accompanied by utmost caution. Even though unclassified obesity seems like an important prognostic factor for ICU admission, findings regarding obesity classes do not support this conclusion. One possible explanation for these contradictory results could be that the decision about ICU admission is made by the treating physician. This subjective decision can be informed by many different factors that are known to physicians, such as obesity. The resulting differential misclassification bias can introduce this unexpected difference. To a lesser degree, this bias can influence our results about mechanical ventilation too.

In terms of hospitalisation, we found moderate-quality evidence that classes I and II of obesity alter the risk of hospitalisation negligibly (-0.05% and 0.07%, respectively). On the other hand, the 3.2% and 5.5% increased risk of hospitalisation for class III and unclassified obesity arise from low certainty in the evidence. Therefore, although obesity might be a prognostic factor for hospitalisation, we do not think it is an important prognostic factor.

The available data for severe COVID-19 disease only showed class I and unclassified obesity associations with this outcome. High-quality evidence suggests that unclassified obesity is an important prognostic factor for severe disease with an increased risk of 12.3%. Similarly, we only found moderate-quality evidence that unclassified obesity is an important prognostic factor for COVID-19 pneumonia with an 8.2% increase in absolute risk.

5.2. Overall completeness and applicability of evidence

In this review, we sought to determine if obesity is an independent prognostic factor for adverse outcomes among adult patients with confirmed COVID-19 infections. Obesity as a prognostic variable is complex and has been examined in different ways, which can complicate interpretation. Part of this complexity also includes using different comparators in analyses, such as those that include or exclude being overweight (BMI 25 to 29.9 kg/m²). Examining obesity as three separate classes, as continuous BMI, and also

assessing the congruency across the various approaches, as we did, may address part of this complexity and provide some of the nuanced details required for clinical and policy decision-making.

Our findings demonstrate clear dose-response relationships between obesity and in-hospital mortality, and obesity and mechanical ventilation amongst adult COVID-19 patients. Unclassified obesity is an important prognostic factor for severe COVID-19 disease and is probably an important prognostic factor for COVID-19 pneumonia. However, findings for ICU admission and hospitalisation had more variability and uncertainty. These findings could be used for risk stratification of COVID-19 patients, and to inform customised clinical management and resource allocation when providing care.

On the flip side of management, taking precautions to minimise the risk for infection with COVID-19 is important for everyone, but even more so for certain groups of people, particularly regarding modifiable risk factors. Specifically, our findings indicate that adults living with obesity can be considered a potentially vulnerable group. These findings are, therefore, also relevant for COVID-19 practice and policy decisions around prevention, and may also be informative for decisions around detection and testing. Importantly, the use of these findings for management and prevention decisions should be considered within the context of the roles of other prominent prognostic factors (e.g. age).

Based on the exclusion criteria of the included studies, the findings of this review are specifically most applicable to adults living with obesity who have been hospitalised with confirmed COVID-19 infection. Included studies were undertaken in a wide range of countries and amongst people from a wide age range (approximately between 31 and 77 years old on average). Although present in a minority of studies, the following are examples of sub-populations excluded from these studies: pregnant women, nursing home residents, and patients living with severe morbid obesity (e.g. > 300 kg, $BMI > 100 \text{ kg/m}^2$), organ transplants, active cancer, and terminal illnesses. Importantly, a large proportion of included studies did not report their exclusion criteria.

Numerous interdependent prognostic variables for adverse outcomes in COVID-19 patients have been identified, including obesity. A better understanding of whether obesity per se is a key prognostic variable will help to identify vulnerable patients, inform treatment decisions and better allocate limited resources. For these reasons, we only included studies with multivariable analyses and then sought to examine if associations were different between studies using a minimum adjustment set (age, sex, diabetes, hypertension, and cardiovascular disease) compared to those that did not.

5.3. Certainty of the evidence

As evident from the summary of findings tables, we have a variety of evidence quality levels for different comparisons and outcomes. We have started our certainty in the evidence as high for each comparison and subsequently rated the level down for pertinent issues. The most common reasons for downgrading the certainty in the evidence include imprecision and heterogeneity followed by risk of bias. While we did not have problems with the directness of the evidence, suspected publication bias affected some of the ratings. You can refer to the individual summary of findings tables

for each comparison and outcome reasons and explanations for the downgrading of certainty in the evidence.

5.4. Potential biases in the review process

Our review has several notable strengths. We systematically searched all bibliographic databases for studies published in any language. Therefore, our inferences on the prognostic value of obesity, in the setting of COVID-19, are informed by the totality of peer-reviewed publications on this topic. In addition to summarising the individual studies, we critically appraised their risk of bias with the use of QUIPS. Furthermore, for each of WHO's obesity classes, we were able to conduct a separate meta-analysis to obtain a pooled estimate and 95% CI. Beyond the WHO classification, our review also evaluated the prognostic utility of BMI as a continuous variable. Specifically, in evaluating the risk of bias, we determined a minimal set of key covariates (age, diabetes, cardiovascular disease) that authors of primary studies should have adjusted for in their multivariable regression modelling. We used subgroup analyses to evaluate whether this minimal set of key covariates had bearing on the association between obesity and outcomes. The combination of only including studies with multivariate analyses, the use of QUIPS to assess risk of bias (which explicitly incorporates the extent of covariates adjusted for) and the conducting of subgroup analyses based on the adequate adjustment of covariates allowed us to address the complex relationship between obesity and comorbidities in influencing mortality and other adverse COVID-related outcomes. In summarising our findings, we translated the pooled relative effects to absolute risk difference to clinically contextualise the findings of our review. Our review also benefited from the GRADE framework, which informed our certainty in the prognostic value of obesity.

Our review also had several notable limitations. We continuously strived to maintain an updated list of eligible articles. We did this by repeating our search and screening multiple times in the conduct of this systematic review. Despite our best efforts, however, we were unable to keep up with the rapid pace of publications on COVID-19. Therefore, by the time this review is completed, several new articles may be published that are eligible for inclusion but not within our review. To date, our search has captured studies published up to April 2021. These additional studies may have variable impact on the outcomes reported in our review. We believe that additional studies may have minimal impact on the pooled estimates for mortality and mechanical ventilation. These outcomes had the highest number of patients and events, and thus the inclusion of additional studies may minimally impact on our findings. This, however, is not the case for other outcomes (such as ICU admission, hospitalisation, and severe COVID-19), which were informed by much fewer studies. The inclusion of additional studies published after April 2021 may introduce an additional source of heterogeneity: inclusion of studies following cohorts of patients previously vaccinated for COVID-19. Another point to mention is that, in the case of missing data, we did not contact the authors of the original works. However, this can also have minimal impact on the results based on the previously mentioned reasons.

In our review, the included primary studies, in their multivariable regression modelling, adjusted for different types of covariates. Seldom did we observe two studies adjusting for the exact set of covariates, and some studies only adjusted for a single covariate. Although we prespecified a set of important covariates that authors

should adjust for (as part of our risk of bias assessment, including age, sex, diabetes, hypertension, and cardiovascular disease), considerable heterogeneity exists in the covariates adjusted for. A notable limitation of our review is that we were unable to explore this methodologic heterogeneity beyond the exploration of subgroups. The most ideal method for dealing with this source of heterogeneity is to conduct a meta-analysis of individual patient data. These differing covariates may be a contributing factor to the observed inconsistency, beyond random error, observed in meta-analyses for mechanical ventilation, ICU admission, and hospitalisation. To account for and acknowledge this degree of heterogeneity, we ensured that we conducted all our meta-analyses under the random-effects framework. Furthermore, we acknowledge the doubt created by heterogeneity in assessing our certainty in the prognostic value of obesity.

Finally, the findings of our review are dependent on the underlying assumption that BMI is a meaningful and valid measure to capture obesity and its severity. The relationship between BMI and percentage of body fat is non-linear, and the measure does not account for nonfat sources of mass (e.g. bone, muscle), the natural changes in body composition that accompany age, and the natural differences in body composition across different ethnicities (Hall 2006; Rothman 2008). Furthermore, there are differences between self-reported and measured BMI (Maukonen 2018). However, despite these limitations, BMI remains the predominant measure of an individual's adiposity due to its ease of use and relatively low cost of collection (Burkhauser 2008). BMI was selected as the measure of obesity in our review due to its widespread use, however, we acknowledge the bias that the measure may bring when evaluating obesity's prognostic value.

5.5. Agreements and disagreements with other studies or reviews

Since the beginning of the COVID-19 pandemic, multiple systematic reviews have strived to investigate the association of obesity with adverse outcomes of COVID-19 disease. However, the methodologic quality, number of included studies, and reporting of these studies vary.

Dessie 2021 included a total of 423,117 participants from a total of 42 studies in their review to locate mortality-related risk factors of COVID-19. Their quantitative analysis of 11 studies concluded with an OR of 1.34 (95% CI 1.17 to 1.52) and an HR of 1.5 (95% CI 1.26 to 1.75) for patients with obesity versus those without. These results are in line with our calculated pooled OR for obesity unclassified (OR 1.35, 95% CI 1.28 to 1.42). However, there are methodological concerns with this study. For example, the study did not mention any protocol registration or clear eligibility criteria.

Another study, Raeisi 2022, conducted a systematic search in June 2020 (published in July 2021). In contrast to other reviews, this study also evaluated the quality of evidence through the application of GRADE. This study investigated the association of obesity with mortality, mechanical ventilation, ICU admission, and hospitalisation amongst COVID-19 patients. This study found low-quality evidence for mortality, mechanical ventilation, and ICU admission and very low-quality evidence for hospitalisation. Similar to other reviews, authors only compared patients with obesity versus those without further classification of obesity groups. The findings of this study agree with our findings in that they found ORs of 1.23 (95% CI 1.06 to 1.41), 2.24 (95% CI 1.70

to 2.94), 1.75 (95% CI 1.38 to 2.22), and 1.75 (95% CI 1.47 to 2.09) for mortality, mechanical ventilation, ICU admission, and hospitalisation. However, we reported lower ORs for mechanical ventilation and hospitalisation.

Other reviews also had systematic searches from May 2020 to July 2020 (Chu 2020; Földi 2020; Soeroto 2020). These reviews investigated the association between obesity and various outcomes such as mortality, mechanical ventilation, ICU admission, and poor outcomes. Most findings by these reviews were in line with our findings in terms of the association direction. However, Chu 2020 reported a statistically non-significant lower odds for mortality among those with obesity. This study reported an OR of 0.89 (95% CI 0.32 to 2.51, 3856 participants from 3 studies) for patients with obesity versus those without obesity in COVID-19 patients. In addition, another study investigated factors associated with mortality amongst COVID-19 patients admitted to the ICU (Taylor 2021). The study included 21 studies to compare the mean BMI between the deceased and survival groups. What they found was a statistically non-significant difference between the groups (SMD 0.05, 95%CI -0.06 to 0.16). It is noteworthy that an asymmetry in their forest plot suggests the possibility of publication bias.

AUTHORS' CONCLUSIONS

6.1. Implications for practice

Our findings are most applicable to adults living with obesity who have been hospitalised with confirmed COVID-19 infection. In these patients, the evidence suggests clear dose-response relationships between obesity and in-hospital mortality, and obesity and mechanical ventilation. Unclassified obesity is an important prognostic factor for severe COVID-19 disease and is probably an important prognostic factor for COVID-19 pneumonia. However, findings for ICU admission and hospitalisation were less clear. These findings could be used to inform risk stratification of adult COVID-19 patients for the provision of clinical care, allocation of resources, and planning prevention, detection, and testing strategies.

6.2. Implications for research

As the findings of our review suggest, obesity is an important prognostic factor for at least some of the patient-important COVID-19 adverse outcomes. Therefore, it is important that future research acknowledge this fact and clearly report on their population in regard to obesity. Another important consideration is for researchers to ensure that patients with obesity should be sufficiently represented in trials on COVID-19 treatments and vaccines. To ensure this, any systematic exclusion of this group should only take place with a strong rationale and in exceptional circumstances. Finally, our review demonstrates the variability in covariates adjusted for across studies exploring obesity as a prognostic factor amongst patients diagnosed with COVID-19. Future individual patient data meta-analyses are needed to explore the independent association of obesity and COVID-19 outcomes under a controlled set of covariates.

ACKNOWLEDGEMENTS

We would like to commemorate one of the authors of this review who we lost during the conduct of this review. Dr. Kamran Shokraee was a bright young man with great aspirations who contributed

to this review with unparalleled enthusiasm and sincerity. Even though his departure was very sudden, saddening, and shocking to his family and friends, his great achievements in academic and social life will be remembered. He not only represented the true meaning of academic excellence but touched many lives through his compassion. Kamran was a caring teacher, curious researcher, compassionate doctor, and a loving brother and friend. Although his journey was short in this world, his memory will linger with us forever.

This study was part of Dr. Borna Tadayon Najafabadi's thesis work for Ph.D. in Health Research Methodology at McMaster University.

AS and CEN are partly supported by the Research, Evidence and Development Initiative (READ-It). READ-It (project number 300342-104) is funded by UK aid from the UK government; however, the views expressed do not necessarily reflect the UK government's official policies.

Cochrane Metabolic and Endocrine Disorders Groups supported the authors in the development of this review. The following people conducted the editorial process for this article

- Sign-off Editor (final editorial decision): Brenda Bongerts, Coordinating editor at the Cochrane Metabolic and Endocrine Disorders group
- Managing Editor (selected peer reviewers, provided comments, collated peer-reviewer comments, provided editorial guidance to authors, edited the article): Lara Kahale and Colleen Ovelman, Cochrane Central Editorial Service
- Editorial Assistant (conducted editorial policy checks and supported editorial team): Lisa Wydrzynski, Cochrane Central Editorial Service
- Copy Editor (copy-editing and production): [NAME, AFFILIATION] (will be identified later)
- Peer-reviewers (provided comments and recommended an editorial decision): Carmen Piernas, MSc PhD; University Research Lecturer, University of Oxford (content review), Robert Walton. Senior Fellow in General Practice, Cochrane UK (content review); Kerry Dwan, Cochrane Methods Support Unit (methods review); and Robin Featherstone, Cochrane Central Editorial Service (search review).

One additional peer reviewer provided content peer review, but chose not to be publicly acknowledged

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Abumayyaleh 2021

Study characteristics

Notes	English title
	Does there exist an obesity paradox in COVID-19? Insights of the international HOPE-COVID-19-registry
	Study setting
	Start of study recruitment (MM/YYYY)
	NR
	End of study recruitment (MM/YYYY)
	05/2020
	Study design
	retrospective cohort
	Study centre(s)
	international
	Number of centres/clinics/areas
	21
	Study setting
	inpatient
	Number of participants recruited
	3635
	Sampling method
	consecutive participants
	Participants
	Female participants
	(absolute number), 1518
	Age measure, value
	median (range), 63 (18, 99)
	Central tendency measure of age

Study characteristics

Notes	English title The Swedish Covid-19 intensive care cohort: risk factors of ICU admission and ICU mortality
	Study setting
	Start of study recruitment (MM/YYYY): NR
	End of study recruitment (MM/YYYY): 05/2020
	Study design: Case-control
	Study centre(s): Multiple centres/clinics/areas within a country
	Number of centres, clinics or areas: NR
	Study setting: Inpatient
	Number of participants recruited: 1981
	Sampling method: Consecutive participants
	Participants
	Female participants (absolute number): 516
	Age measure, value: Median (IQR), 61 (52-69)
	Inclusion criteria: The study population was defined by at least one COVID-19 registration in the SIRI until data acquisition on 27 May 2020. From RTB, four age- and sex-matched controls per patient were drawn. Age matching was performed as close to ICU admission as possible, on the age at 31 January 2020. Cases could not become controls and controls could not be selected twice.
	Exclusion criteria: Exclusion criteria were aged < 18 years or the absence of a Swedish personal identification number (PIN)
	Smoking frequency: NR
	Diabetes frequency: 522
	Hypertension frequency: 982
	Cardiovascular disease frequency: 317

Inclusion criteria

The criteria for hospitalisation according to the Ministry of Health concerned the individual presenting gripal syndrome along with dyspnoea/respiratory distress or persistent pressure in the chest or blood oxygen saturation < 95% in room air or blue lips/face. The gripal syndrome concerned the individual with an acute respiratory condition, characterised by at least two of the following signs and symptoms: fever (even if referred), chills, sore throat, headache, cough, runny nose, olfactory disorders or taste disorders. We used in our study data from 162,045 patients who had closed outcomes (cure or death) in order to provide a profile overview of the patients and after, a 44,128 patient cohort with full symptom/comorbidity information aiming to analyse risk factors for mortality.

Multivariable analysis for obesity

Modelling method: Logistic regression

The set of prognostic factors used for adjustment: Active cancer, age, body mass index (calculated as weight in kilograms divided by height in meters squared), chronic obstructive pulmonary disease, congestive heart failure, coronary artery disease, covariates assessed at ICU admission (lymphocyte count, ratio of the PaO₂ to the fraction of inspired oxygen [FIO₂], shock, and the kidney, liver, and coagulation components of the Sequential Organ Failure Assessment score), current smoking status, diabetes, duration of symptoms before ICU admission, hypertension, sex, race

Effect measure for obesity: Odds ratio

Effect measure value (95% CI), P value: 1.51 (1.01, 2.25), NR

Hosseinzadeh 2021
Study characteristics

Notes	English title

Hosseinzadeh 2021 (Continued)

Should all patients with hypertension be worried about developing severe coronavirus disease 2019 (COVID-19)?

Study setting

Start of study recruitment (MM/YYYY): NR

End of study recruitment (MM/YYYY): NR

Study design: retrospective cohort

Study centre(s): Single centre/clinic/area within a country

Number of centres, clinics or areas: 1

Study setting: Inpatient

Number of participants recruited: 176 (cohort 1), 422 (cohort 2)

Sampling method: NR

Participants

Female participants (absolute number): 115 (cohort 1), 289 (cohort 2)

Age measure, value: Mean (SD), 58.21 (22.5) (cohort 1), 56.15 (20.2) (cohort 2)

Inclusion criteria: Cases with COVID-19 pneumonia who were admitted to Baqiyatallah Hospital in Tehran – Iran

Exclusion criteria: Incomplete medical profiles, patients who were not receiving any kind of anti-hypertensive medications and patients who were receiving any corticosteroids

Smoking frequency: 4 (cohort 1), 12 (cohort 2)

Diabetes frequency: 72 (cohort 1), 76 (cohort 2)

Hypertension frequency: 176 (cohort 1), 0 (cohort 2)

Cardiovascular disease frequency: 63 (cohort 1), 44 (cohort 2)

Asthma frequency: 31 (cohort 1), 67 (cohort 2)

Chronic obstructive pulmonary disease frequency: NR

Other pulmonary disease frequency: 36 (cohort 1), 52 (cohort 2)

Immunosuppression frequency: NR

Chronic kidney disease frequency: 25 (cohort 1), 33 (cohort 2)

Cancer frequency: 4 (cohort 1), 8 (cohort 2)

Steroid administration frequency: NR

Supplemental oxygen administration frequency: NR

Other treatments (frequency): NR

Comment: Asthma consists of both asthma and allergy history

Prognostic factor(s)

Study's definition for obesity: BMI > 25 kg/m²

The time when obesity has been measured: NR

Hosseinzadeh 2021 (Continued)

Main variable used for determination of obesity: NR

Threshold used for definition: NR

Obesity frequency (absolute number): NR

Prognostic factor(s): Overweight/obesity

Outcome(s)

Severe COVID-19

Outcome (prognostic factor)

Severe COVID-19 (overweight/obesity) (cohort1)

Follow-up

Number of patients followed completely for the outcome: 176

Number of obese patients followed completely for the outcome: NR

Number of non-obese patients followed completely for the outcome: NR

Univariable unadjusted analysis for obesity

Effect measure for obesity: NR

Effect measure value (95% CI), P value: NR

Multivariable analysis for obesity

Modelling method: Logistic regression

The set of prognostic factors used for adjustment: Age > 60 years, BMI > 25 kg/m², increased hospital stays, CVD, diabetes, kidney disease

Effect measure for obesity: Odds ratio

Effect measure value (95% CI), P value: 1.80 (1.02, 2.42), 0.027

Outcome (prognostic factor)

Severe COVID-19 (overweight/obesity) (cohort2)

Follow-up

Number of patients followed completely for the outcome: 422

Number of obese patients followed completely for the outcome: NR

Number of non-obese patients followed completely for the outcome: NR

Univariable unadjusted analysis for obesity

Effect measure for obesity: NR

Effect measure value (95% CI), P value: NR

Multivariable analysis for obesity

Modelling method: Logistic regression

The set of prognostic factors used for adjustment: Age > 60 years, BMI > 25 kg/m², increased hospital stays, CVD, diabetes, kidney disease

Effect measure for obesity: Odds ratio

Hosseinzadeh 2021 (Continued)

	Obesity as an independent risk factor for COVID-19 severity and mortality (Review)

Kim 2020b (Continued)

Analysis of mortality and morbidity in COVID-19 patients with obesity using clinical epidemiological data from the Korean Center for Disease Control & Prevention

Study setting

Start of study recruitment (MM/YYYY): NR

End of study recruitment (MM/YYYY): 06/2020

Study design: Registry data

Study centre(s): NR

Number of centres, clinics or areas: NR

Study setting: NR

Number of participants recruited: 4027

Sampling method: Consecutive participants

Participants

Female participants (absolute number): 2334

Age measure, value: NR

Inclusion criteria: Patients with confirmed cases of COVID-19 was released from isolation after achieving a complete recovery. Asymptomatic patients were determined to be completely recovered if the PCR results were negative two consecutive times with at least a 24-h interval between them at least seven days after a definitive diagnosis had been made. Symptomatic patients with confirmed cases were determined to be completely recovered if they had no fever without taking antipyretic drugs, the clinical manifestations were improved and the PCR results were negative two consecutive times with at least a 24-h interval between them at least seven days after a definitive diagnosis had been made.

Exclusion criteria: Participants who did not have records of symptoms or past medical histories were excluded. Participants who did not have recorded BMI values were excluded.

Smoking frequency: NR

Notes	English title
	Severe obesity as an independent risk factor for COVID-19 mortality in hospitalized patients younger than 50
	Study setting
	Start of study recruitment (MM/YYYY): 03/2020
	End of study recruitment (MM/YYYY): 05/2020
	Study design: Registry data
	Study centre(s): Multiple centres/clinics/areas within a country
	Number of centres, clinics or areas: 5
	Study setting: Inpatient
	Number of participants recruited: 572 (cohort 1), 2834 (cohort 2)
	Sampling method: Consecutive participants
	Participants
	Female participants (absolute number): 175 (cohort 1), 1270 (cohort 2)
	Age measure, value: NR
	Inclusion criteria: All adult patients who were positive for COVID-19 by nasopharyngeal swab polymerase chain reaction test and were admitted to the hospital. Patients who were discharged or had died during the study period were included.
	Exclusion criteria: Patients who were still hospitalised at the time of analysis and patients with missing BMI data
	Smoking frequency: 76 (cohort 1), 717 (cohort 2)
	Diabetes frequency: 153 (cohort 1), 1446 (cohort 2)

Klang 2020 (Continued)

Hypertension frequency: 175 (cohort 1), 2124 (cohort 2)

Cardiovascular disease frequency: 67 (cohort 1), 1190 (cohort 2)

Asthma frequency: NR

Chronic obstructive pulmonary disease frequency: NR

Other pulmonary disease frequency: NR

Immunosuppression frequency: NR

Chronic kidney disease frequency: 70 (cohort 1), 597 (cohort 2)

Steroid administration frequency: NR

Supplemental oxygen administration frequency: 79 (cohort 1), 730 (cohort 2)

Other treatments (frequency): NR

Prognostic factor(s)

Study's definition for obesity: Obesity was defined as $BMI \geq 30 \text{ kg/m}^2$; obesity groups included the following: BMI of 30 to < 40 and $BMI \geq 40$

The time when obesity has been measured: Before disease or right at presentation

Main variable used for determination of obesity: BMI

Threshold used for definition: 30

Obesity frequency (absolute number): 275 (cohort 1), 956 (cohort 2)

Prognostic factor(s): BMI of 30 to < 40

$BMI \geq 40$

Prognostic factor(s)**Study's definition for obesity**

Obesity (body mass index $\geq 30 \text{ kg/m}^2$) is frequently categorised into three categories: class 1 (30.0–34.9 kg/m^2), class 2 (35.0–39.9 kg/m^2), and class 3 ($\geq 40 \text{ kg/m}^2$). Class 3 obesity is sometimes referred to as “extreme” or “severe” obesity.

Nutritional risk and therapy for severe and critical COVID-19 patients: a multicenter retrospective observational study

Study setting

Start of study recruitment (MM/YYYY): 01/2020

End of study recruitment (MM/YYYY): 02/2020

Study design: Retrospective cohort

Study centre(s): Multiple centres/clinics/areas within a country

Number of centres, clinics or areas: 4

Study setting: Inpatient

Number of participants recruited: 523

Sampling method: Consecutive participants

Participants

Female participants (absolute number): 273

Age measure, value: Mean (SD), 54.2 (15.9)

Inclusion criteria: Severely ill patients if they met any of the following criteria: 1. respiratory distress and respiratory rate was \geq 30 times/min, 2. oxygen saturation in a resting state was \leq 93%, 3. arterial partial pressure of oxygen (PaO_2)/fraction of inspired oxygen (FiO_2) was \leq 300 mm Hg; critically ill patients if they met any of the following criteria: 1. respiratory failure and need for mechanical ventilation, 2. shock, and 3. other organ failure requiring ICU monitoring. Positive results for real-time polymerase chain reaction testing of respiratory or blood samples were defined as confirmed cases. The inclusion time was from January 2, 2020 to February 15, 2020 for discharged and dead patients.

Mehta 2021a (Continued)

Participants**Female participants**

(absolute number), 90,501

Age measure, value

mean (standard deviation), 82.7 (9.2)

Inclusion criteria

We identified long-stay residents aged 65 years and older residing in nursing homes as of April 1, 2020. We identified nursing home stays based on the MDS data and excluded any skilled nursing facility care during that stay. We restricted nursing home residents to those with continuous enrolment in Medicare Parts A and B with no enrolment in health maintenance organisations from April 1, 2020, until SARS-CoV-2 diagnosis, death, or the study end date on September 30, 2020. We included characteristics if there were a priori reasons why they might be associated with increased risk of SARS-CoV-2 infection, such as a condition that might necessitate more physical contact by staff or that might interfere with following instructions on social distancing. We also included characteristics associated with risk of hospitalisation or death in prior studies.

Exclusion criteria

We excluded residents if they were diagnosed with SARS-CoV-2 before April 1, 2020 using ICD-10-CM codes of J12.89, J20.8, J40, J22 J98.8, J80 combined with B97.29, or U07.1 to identify SARS-CoV-2.

Notes

English title

Factors associated with clinical severity in emergency department patients presenting with symptomatic SARS-CoV-2 infection.

Study setting

Start of study recruitment (MM/YYYY): 03/2020

End of study recruitment (MM/YYYY): 08/2020

Study design: Case-series

Study centre(s): Single centre/clinic/area within a country

Number of centres, clinics or areas: 1

Study setting: Outpatient and inpatient

Number of participants recruited: 993

Sampling method: NR

Participants

Female participants (absolute number): 504

Age measure, value: Mean (SD), 52.09 (18.1)

Inclusion criteria: Patients were included in this analysis if they presented to the ED with a chief complaint(s) consistent with COVID-19 and they tested positive for SARS-CoV-2 by nasopharyngeal swab using a polymerase chain reaction (PCR) platform.

Exclusion criteria: Patients with positive SARS-CoV-2 results who were tested by protocol for another condition unrelated to COVID-19 such as trauma, intoxication, poisoning, suicidality, involuntary commitment, or isolated complaints highly unlikely to be related to COVID-19 (e.g. suture removal) were not included in this analysis. Additionally, asymptomatic, swab-positive patients tested for reasons other than a clinician's suspicion of COVID-19 disease were not included in this study.

Inclusion criteria

All patients included in this cohort had a positive real-time reverse transcription-polymerase chain reaction (PCR) either from a naso/oropharyngeal swab or from a tracheal aspirate by a procedure previously described, chest computed tomography scan compatible with diagnosis of COVID-19 pneumonia, routine blood workup (including complete blood count, inflammatory markers, metabolic panel and arterial blood gas analysis) and required hospital admission due to hypoxaemia.

Exclusion criteria

143 patients (14%) did not meet inclusion criteria due to negative or indeterminate SARS-CoV-2 PCR results, we excluded 62 patients due to inter-hospital transfer and unknown clinical outcome (transfer to another hospital with available ICU beds owing to clinical deterioration) and 13 patients that were discharged against medical advice.

Omraní 2020
Study characteristics

Notes	English title
The first consecutive 5000 patients with Coronavirus Disease 2019 from Qatar; a nation-wide cohort study	
	Study setting
	Start of study recruitment (MM/YYYY): 02/2020
	End of study recruitment (MM/YYYY): 04/2020
	Study design: Retrospective cohort
	Study centre(s): Multiple centres/clinics/areas within a country
	Number of centres, clinics or areas: NR

Omrani 2020 (Continued)

Study setting: Outpatient and inpatient

Number of participants recruited: 5000

Sampling method: Consecutive participants

Participants

Female participants (absolute number): 564

Age measure, value: Median (IQR), 35 (28, 43)

Inclusion criteria: The first consecutive 5000 patients with RT-PCR-confirmed COVID-19 who would complete 60 days of follow up from date of diagnosis

Exclusion criteria: NR

Smoking frequency: NR

Diabetes frequency: 470

Hypertension frequency: 476

Cardiovascular disease frequency: 61

Asthma frequency: NR

Chronic obstructive pulmonary disease frequency: NR

Other pulmonary disease frequency: 156

Immunosuppression frequency: NR

Chronic kidney disease frequency: 44

Cancer frequency: 31

Steroid administration frequency: NR

Supplemental oxygen administration frequency: NR

Other treatments (frequency): NR

Prognostic factor(s)

Study's definition for obesity: Body mass index (BMI), defined as body weight in kilograms divided by squared height in metres

The time when obesity has been measured: Before disease or right at presentation

Main variable used for determination of obesity: BMI

Threshold used for definition: Not applicable

Obesity frequency (absolute number): NR

Prognostic factor(s): BMI (per 1 kg/m² increase)

Outcome(s)

ICU admission

Outcome (prognostic factor)

ICU admission (BMI (per one kg/m² increase))

Follow-up

Omrani 2020 (Continued)

Number of patients followed completely for the outcome: 1409

Number of obese patients followed completely for the outcome: NR

Number of non-obese patients followed completely for the outcome: NR

Univariable unadjusted analysis for obesity

Effect measure for obesity: Odds ratio

Effect measure value (95% CI), P value: 1.067 (1.033, 1.102), < 0.001

Multivariable analysis for obesity

Modelling method: Logistic regression

The set of prognostic factors used for adjustment: The final multivariable logistic regression model included age, male sex, body mass index (BMI), defined as body weight in kilograms divided by squared height in metres, and co-existing diabetes mellitus, systemic hypertension, coronary artery disease, chronic liver disease, and chronic kidney disease.

Effect measure for obesity: Odds ratio

Effect measure value (95% CI), P value: 1.067 (1.027, 1.108), 0.001

Pablos 2020
Study characteristics

Notes	English title	
	Clinical outcomes of hospitalized patients with COVID-19 and chronic inflammatory and autoimmune rheumatic diseases: a multicentric matched cohort study	
	Study setting	
	Start of study recruitment (MM/YYYY):	NR
	End of study recruitment (MM/YYYY):	04/2020

Pablos 2020 (Continued)

Study design: Retrospective cohort

Study centre(s): Multiple centres/clinics/areas within a country

Number of centres, clinics or areas: 5

Study setting: Inpatient

Number of participants recruited: 456

Sampling method: NR

Participants

Female participants (absolute number): 133

Age measure, value: Mean (SD), 64 (17.74)

Inclusion criteria: The rheumatology cohort included all adult patients diagnosed with chronic inflammatory arthritis (IA), including rheumatoid arthritis, psoriatic arthritis (PsA) and spondylarthritis (SpA); CTD, including systemic lupus erythematosus (SLE), Sjögren's syndrome (SS), systemic sclerosis, polymyalgia rheumatica (PMR), vasculitis and so on (online supplementary table S1) with a PCR + COVID-19 diagnosis. The control cohort was assembled from the Microbiology databases of the participating centres matched on a 1:1 basis with the rheumatic cohort on the date of COVID-19 diagnosis ('index date'), sex and age, and blinded to outcome or other variables.

Exclusion criteria: In the control cohort, patients with CTD were excluded.

Smoking frequency: NR

Diabetes frequency: 85

Hypertension frequency: 210

Cardiovascular disease frequency: 106

Asthma frequency: NR

Chronic obstructive pulmonary disease frequency: NR

Other pulmonary disease frequency: 93

Immunosuppression frequency: NR

Chronic kidney disease frequency: NR

Cancer frequency: NR

Steroid administration frequency: 110

Supplemental oxygen administration frequency: 260

Other treatments (frequency): NR

Prognostic factor(s)

Study's definition for obesity: NR

The time when obesity has been measured: Before disease or right at presentation

Main variable used for determination of obesity: Unspecified

Threshold used for definition: NR

Obesity frequency (absolute number): 109

Prognostic factor(s): Obesity

Pablos 2020 (Continued)
Outcome(s)

Severe COVID

Outcome (prognostic factor)

Severe COVID (obesity)

Follow-up

Palaiodimos 2020
Study characteristics

Notes	English title

Palaiodimos 2020 (Continued)

Severe obesity, increasing age and male sex are independently associated with worse in-hospital outcomes, and higher in-hospital mortality, in a cohort of patients with COVID-19 in the Bronx, New York

Study setting

Start of study recruitment (MM/YYYY): 03/2020

End of study recruitment (MM/YYYY): 03/2020

Study design: Retrospective cohort

Study centre(s): Single centre/clinic/area within a country

Number of centres, clinics or areas: 1

Study setting: Inpatient

Number of participants recruited: 200

Sampling method: Consecutive participants

Participants

Female participants (absolute number): 102

Age measure, value: Median (IQR), 64 (50-73.5)

Inclusion criteria: The first patients who presented to the emergency room (ER) and were admitted to the inpatient medicine service or the intensive care unit (ICU) with laboratory-confirmed COVID-19

Exclusion criteria: 1. Discharge home directly from the ER, 2. Transfer to the centre after having received care in other institutions, 3. Admission for non-COVID-19 related reasons or non-medical reasons (e.g. patients admitted because of a fracture, clinically stable patients residing in group homes unable to self-isolate)

Smoking frequency: 65

Diabetes frequency: 79

Hypertension frequency: 152

Cardiovascular disease frequency: 34

Asthma frequency: 27

Chronic obstructive pulmonary disease frequency: 28

Other pulmonary disease frequency: NR

Immunosuppression frequency: 5

Chronic kidney disease frequency: 58

Cancer frequency: 11

Steroid administration frequency: NR

Supplemental oxygen administration frequency: NR

Other treatments (frequency): 17 (immunosuppressive therapy)

Prognostic factor(s)

Study's definition for obesity: Three groups based on the BMI: BMI < 25 kg/m², BMI 25–34 kg/m², and BMI ≥ 35 kg/m²

The time when obesity has been measured: Before disease or right at presentation

Palaiodimos 2020 (Continued)

Recalde 2020
Study characteristics

Notes	English title Body mass index and risk of COVID-19 diagnosis, hospitalisation, and death: a population-based multi-state cohort analysis including 2,524,926 people in Catalonia, Spain
	Study setting
	Start of study recruitment (MM/YYYY): 03/2020
	End of study recruitment (MM/YYYY): 05/2020
	Study design: Retrospective cohort
	Study centre(s): Multiple centres/clinics/areas within a country
	Number of centres, clinics or areas: NR
	Study setting: Outpatient and inpatient

Recalde 2020 (Continued)

Number of participants recruited: 57,443

Sampling method: Consecutive participants

Participants

Female participants (absolute number): 35,236

Age measure, value: Median (IQR), 48 (38-60)

Inclusion criteria: All adults (aged 18 years or older) registered in the SIDIAP as of the 1st March 2020 with a BMI recorded at an age equal or greater than 18 years. Individuals with at least one year of prior history available, without a previous clinical diagnosis or positive test result for COVID-19, who were not hospitalised or living in a nursing home on the 1st March 2020 (to have study participants representative of the community population) and who had information on both smoking and socioeconomic status

Exclusion criteria: Individuals who had less than a year of prior clinical history; who had a prior COVID-19 clinical diagnosis or positive test; who were hospitalised or living in a nursing home on March 1st; who had the unavailability of a BMI measurement; and who had missing data on smoking status and/or the MEDEA deprivation index

Smoking frequency: 47,340

Diabetes frequency: 4327

Hypertension frequency: 9923

Cardiovascular disease frequency: 7083

Asthma frequency: NR

Chronic obstructive pulmonary disease frequency: 1622

Other pulmonary disease frequency: NR

Immunosuppression frequency: NR

Chronic kidney disease frequency: 2500

Cancer frequency: 3588

Steroid administration frequency: NR

Supplemental oxygen administration frequency: NR

Other treatments (frequency): NR

Prognostic factor(s)

Study's definition for obesity: Obesity was defined based on World Health Organization (WHO) categories of BMI (underweight or normal weight [BMI < 18.5 kg/m²] and between 18.5 and < 25 kg/m²], overweight [BMI ≥ 25 and < 30 kg/m²] and obesity [BMI ≥ 30 kg/m²]).

The time when obesity has been measured: Before disease or right at presentation

Main variable used for determination of obesity: BMI

Threshold used for definition: 30

Obesity frequency (absolute number): 15143

Prognostic factor(s): BMI = 16 kg/m²

BMI = 19 kg/m²

Recalde 2020 (Continued)

BMI = 25 kg/m²

BMI = 28 kg/m²

BMI = 31 kg/m²

Age measure, value

mean (standard deviation), 65.8 (16.26)

Inclusion criteria

We identified patients 18 years of age and older who were admitted between March 19th and April 25th, 2020 with COVID-19 disease and high oxygen requirements. We considered patients to have a high oxygen requirement if they developed acute hypoxaemic respiratory failure and required intubation with mechanical ventilation or needed high-level oxygen supplementation (face mask at more than 10 L per minute, high-flow nasal cannula (HFNC), or non-rebreather (NRB) oxygen face mask) at the time of admission or during hospitalisation.

Exclusion criteria

We excluded patients not requiring high concentrations of oxygen, patients who died within 1 day of being admitted, and those who died during their emergency room stay.

Prognostic factor(s)**Study's definition for obesity**

The categories of BMI were defined as underweight ($BMI < 18.4 \text{ kg/m}^2$), normal-weight ($18.5 \leq BMI \leq 24.9 \text{ kg/m}^2$), overweight ($25.0 \leq BMI \leq 29.9 \text{ kg/m}^2$), and obese ($BMI > 30 \text{ kg/m}^2$)

	Demographics, comorbidities and outcomes in hospitalized Covid-19 patients in rural southwest Georgia
	Study setting
	Start of study recruitment (MM/YYYY): 03/2020
	End of study recruitment (MM/YYYY): 05/2020
	Study design: Retrospective cohort
	Study centre(s): Multiple centres/clinics/areas within a country
	Number of centres, clinics or areas: 3
	Study setting: Inpatient
	Number of participants recruited: 522

Shah 2020 (Continued)

Sampling method: Non-random sample

Participants

Female participants (absolute number): 304

Age measure, value: Median (IQR), 63 (50-72)

Inclusion criteria: All hospitalised patients with confirmed Covid-19, who had an outcome, were included. The outcome was defined as either discharge from the hospital (home, nursing home, long-term care facility, skilled nursing facility, county jail) or death.

Exclusion criteria: Hospitalised patients who did not have an outcome by 6 May 2020 were excluded. The patients transferred to another hospital (due to the hospital being at full capacity or need for treatment not available at the facility) were not included as well.

Inclusion criteria

Patients 18 years of age or older who had an initial visit from March 18, 2020 through April 25, 2020 at our ambulatory clinic and had a positive result of a nasopharyngeal swab for SARS-CoV-2 using the CDC 2019-Novel Coronavirus RT-PCR Diagnostic Panel kit were included in the analytic sample. Patients were considered hospitalised if they were admitted to any hospital, not limited to our network. Patients evaluated and discharged by emergency departments and patients hospitalised for childbirth were considered non-hospitalised for the purposes of our study.

Exclusion criteria

Patients who were initially evaluated in the emergency department were excluded.

	consecutive participants
	Participants
	Female participants
	(absolute number), 10,446
	Age measure, value
	median (interquartile range), 61 (17)
	Inclusion criteria
	Adult patients with T2DM hospitalised and with confirmed COVID-19 infection from 11 March to 30 May 2020 in the Turkish Ministry of Health database
	Exclusion criteria
	We excluded subjects who received outpatient care (n = 85,317), patients with type 1 DM (n = 370), and those unclassified for the diagnosis of DM (n = 715). In the remaining population, there were 18,621 inpatients with T2DM diagnosis screened using the International Classification of Diseases and Related Health Problems, Tenth Revision (ICD-10) codes and 44,648 inpatients without T2DM diagnosis. Patients with a T2DM diagnosis without any glycosylated haemoglobin (HbA1c) measurement within the past 12 months (n = 9408) were excluded.

Inclusion criteria

All adult patients (≥ 18 years old) with COVID-19 confirmed by reverse transcriptase-polymerase chain reaction (RT-PCR) who had a documented BMI 3 months prior to or at admission were included.

Exclusion criteria

Multiple visits from one patient were considered as one COVID-19 episode. Patients who were discharged from the emergency department with or without admission to the observation unit were excluded.

Smoking

NR

Diabetes

(absolute number), 1134

Hypertension

Study characteristics

Notes

English title

Clinical characteristics and outcomes of critically ill patients with COVID-19 admitted to an intensive care unit in London: a prospective observational cohort study

Study setting

Start of study recruitment (MM/YYYY): 03/2020

End of study recruitment (MM/YYYY): 05/2020

Study design: Prospective cohort

Study centre(s): Single centre/clinic/area within a country

Number of centres, clinics or areas: 1

Study setting: Inpatient

Number of participants recruited: 156

Sampling method: Consecutive participants

Participants

Female participants (absolute number): 44

Age measure, value: Median (IQR), 62 (54, 70)

Inclusion criteria: All patients with laboratory-confirmed SARS-CoV-2 infection admitted to the ICU from the first case until the cut-off date for this study, 6 May 2020

Exclusion criteria: NR

Smoking frequency: 117

Diabetes frequency: 52

Hypertension frequency: 81

Cardiovascular disease frequency: 26

Asthma frequency: NR

Chronic obstructive pulmonary disease frequency: NR

Other pulmonary disease frequency: 19

Immunosuppression frequency: NR

Chronic kidney disease frequency: 23

Cancer frequency: NR

Steroid administration frequency: NR

Supplemental oxygen administration frequency: NR

Other treatments (frequency): NR

Prognostic factor(s)

Study's definition for obesity: Overweight or obese ($BMI \geq 25 \text{ kg/m}^2$)

Thomson 2020 (Continued)

The time when obesity has been measured: NR

Main variable used for determination of obesity: BMI

Threshold used for definition: 25

Obesity frequency (absolute number): 80

Prognostic factor(s): (BMI \geq 25 kg/m²)

Outcome(s)

Mortality

Outcome (prognostic factor)

Mortality (BMI \geq 25 kg/m²)

Follow-up

Number of patients followed completely for the outcome: 156

Number of obese patients followed completely for the outcome: 89

Number of non-obese patients followed completely for the outcome: 67

Univariable unadjusted analysis for obesity

Effect measure for obesity: Odds ratio

Effect measure value (95% CI), P value: 1.9 (0.87, 4.33), 0.1

Multivariable analysis for obesity

Modelling method: Logistic regression

The set of prognostic factors used for adjustment: Age, ethnicity, lowest P/F ratio on first ICU day, PaCO₂ at time of lowest P/F ratio

Effect measure for obesity: Odds ratio

Effect measure value (95% CI), P value: 3.06 (1.16, 8.74), < 0.029

Age measure, value: Median (IQR), NR

Inclusion criteria: Women who were hospitalised from 1st March 2020 to 31st August 2020. Hospital admission was defined as a hospital stay of 24 hours or longer for any cause, or admission of any duration to give birth. Women were taken as confirmed SARS-CoV-2 if they were hospitalised during pregnancy or within two days of giving birth and had a positive test during or within seven days of admission, or they were symptomatic and had evidence of pneumonia on imaging which was typical of SARS-CoV-2.

Exclusion criteria: Women were excluded if they did not meet this case definition.

Inclusion criteria

A retrospective cohort study analysis was performed on 116 patients with COVID-19 and a positive SARS-CoV-2 test who were admitted to Wuhan Union Hospital from February 2020 to March 2020. All the patients met the diagnostic and typing criteria in the “Diagnosis and Treatment Plan for Novel Coronavirus Pneumonia (trial version 8)” issued by the National Health Commission.

Exclusion criteria

Nineteen patients were excluded for the following reasons: (1) age less than 18 years or more than 85 years; (2) pregnant; (3) lack of complete data.

Prognostic factor(s)**Study's definition for obesity**

BMI was categorised by the definitions as follows: 1) underweight ($\text{BMI} < 18.5 \text{ kg/m}^2$); 2) normal weight ($18.5 \text{--} 23 \text{ kg/m}^2$); 3) overweight ($23 \text{--} 25 \text{ kg/m}^2$); 4) obesity ($\text{BMI} \geq 25 \text{ kg/m}^2$) according to the World Health Organization recommendations for Asian populations. The validity of this definition has been confirmed previously.

Inclusion criteria

For this study, we included participants with a coding of “Proven or high likelihood of infection with a pathogen of Public Health Interest,” reflecting that a preparedness protocol cannot assume a diagnostic test will be available for an emergent pathogen. Participants were included in the analysis if information was available on hospital admittance date from the emergence of the COVID-19 pandemic in the United Kingdom (UK) (February 6, 2020), confirmed COVID-19 positive, complete outcome data (discharge/in-hospital mortality, ethnicity)

Study characteristics
Obesity as an independent risk factor for COVID-19 severity and mortality (Review)

Copyright © 2023 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Yazdanpanah 2021 (Continued)**Notes****English title**

Impact on disease mortality of clinical, biological, and virological characteristics at hospital admission and overtime in COVID-19 patients

Study setting

Start of study recruitment (MM/YYYY): 01/2020

End of study recruitment (MM/YYYY): 03/2020

Study design: Prospective cohort

Study centre(s): Multiple centres/clinics/areas within a country

Number of centres, clinics or areas: 25

Study setting: Inpatient

Number of participants recruited: 246

Sampling method: Consecutive participants

Participants

Female participants (absolute number): 107

Age measure, value: Median (IQR), 62 (50, 73)

Inclusion criteria: All hospitalised confirmed COVID-19 patients

Exclusion criteria: NR

Smoking frequency: 13

Diabetes frequency: 39

Hypertension frequency: 73

Cardiovascular disease frequency: 48

Asthma frequency: 23

Chronic obstructive pulmonary disease frequency: NR

Other pulmonary disease frequency: 21

Immunosuppression frequency: NR

Chronic kidney disease frequency: 16

Cancer frequency: 14

Steroid administration frequency: 8

Supplemental oxygen administration frequency: 61

Other treatments (frequency): Remdesivir (4%), hydroxychloroquine (3%), lopinavir/ritonavir (27%)

Prognostic factor(s)

Study's definition for obesity: NR

The time when obesity has been measured: Some time after presentation

Main variable used for determination of obesity: BMI

Prognostic factor(s)

Study's definition for obesity

According to the Chinese-specific cut-offs for general adiposity, BMI 18.5–23.9 kg/m² is defined as normal weight, BMI 24.0–27.9 kg/m² as overweight and BMI > 28.0 kg/m² as general obesity.

Appendix 3. Funnel Plots

We presented only the funnel plots for the comparisons that included at least 10 effect estimates. Below you can find the links to each funnel plot and their interpretations:

Mortality and obesity class I analysis funnel plot: [Figure S68](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Mortality and obesity class II analysis funnel plot: [Figure S69](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Mortality and obesity class III analysis funnel plot: [Figure S70](#)

Publication bias: serious. Asymmetrical around pooled estimate in the funnel plot.

Mortality and unclassified obesity analysis funnel plot: [Figure S71](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Mortality and every 5 units increase in BMI analysis funnel plot: [Figure S72](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Mechanical ventilation and obesity class I analysis funnel plot: [Figure S73](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Mechanical ventilation and obesity class III analysis funnel plot: [Figure S74](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Mechanical ventilation and unclassified obesity analysis funnel plot: [Figure S75](#)

Publication bias: serious. Asymmetrical around pooled estimate in the funnel plot.

ICU admission and unclassified obesity analysis funnel plot: [Figure S76](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Hospitalisation and unclassified obesity analysis funnel plot: [Figure S77](#)

Publication bias: serious. Asymmetrical around pooled estimate in the funnel plot.

Hospitalisation and unclassified obesity analysis funnel plot (within minimum adjustment set subgroup): [Figure S78](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

Severe disease and unclassified obesity analysis funnel plot: [Figure S79](#)

Publication bias: not serious. Symmetrical around pooled estimate in the funnel plot.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

To make the review feasible and use more robust methods, we decided to change some of the methods mentioned in the review protocol. These decisions were all made before finishing the data extraction and investigating the study data. All the decisions were made through extensive authors' meetings including methodologists and clinicians. Here we summarise the most important changes from the protocol and our rationale for them.

Initially, to be inclusive of all the study designs that provide similar quality of evidence to answer prognosis questions, we broadened the eligible study designs to also include case-series and registry data. In addition, the astonishing speed of publications around COVID-19 convinced us to include only studies that reported on the outcomes under question by this review. This decision, although uncommon methodologically, was to make the review feasible. Other than these changes, our objective of investigating the independent association between obesity and adverse effects was realised by only including studies that incorporated multivariable analyses.

In the review, we used the QUIPS tool instead of the Newcastle-Ottawa tool. The QUIPS tool is specifically designed to assess the risk of bias in prognostic factor studies. We believe this tool can assess the risk of bias in our included studies better. Furthermore, Riley 2019 and the Cochrane Prognosis group recommend using the QUIPS tool in systematic reviews of prognostic factors.

Additionally, we did not conduct a systematic search of LitCovid in our review. After our search of other electronic databases and sources, we believe that our search was sufficient in capturing all the relevant literature and that an additional search of LitCovid was not necessary.

Another difference between the review and protocol is that we conducted separate meta-analyses for obesity classes and unclassified obesity compared to using the classes as subgroup variables. The predicted number of studies reporting on each class and the clinical relevance of using obesity classes informed this decision. We believe that providing separate effect estimates is more clinically relevant since obesity is not considered only as a binary characteristic in the clinical setting. Furthermore, the lack of sufficient prior knowledge and details in reports compelled us not to undertake subgroup analyses based on other variables.

Because obesity is known to be associated with a number of comorbidities that may affect the outcomes of this review, our review author team, after many discussions, decided to define an adjustment subgroup and investigate the effect of this subgroup on all outcomes.

Finally, we used the statistical methods mentioned before to convert RRs and HRs to ORs. This decision was also made before the data extraction and allowed us to pool data from a wider range of studies in each meta-analysis. This method, in part, led to the possibility of considering separate meta-analyses for obesity classes.
